"Bynotone" is a concentrated nutrient rich in the vitamins *A*, *B* and *D* and other elements which, though often deficient in the ordinary everyday dietary, are of vital importance to nutrition.

"Bynotone" contains essentially—bone marrow, yeast extract, hæmoglobin and liver fat; the latter is prepared by a special process and is the richest known source of vitamin *A*. The natural vitamin content of the ingredients of "Bynotone" is augmented by the addition of a proportion of synthetic vitamin *D*.

"Bynotone" is the ideal accessory food during the ages of active growth and adolescence, the periods of expectant and nursing motherhood and the stage of convalescence after acute disease.

It is a nutrient, hæmatinic and restorative which assists the assimilation of other foods and promotes general good health.

"SMILER"

THE "JACK SPRATT" CHILD.

"Jack Spratt could eat no fat"

Nervous children, the "Jack Spratts" of the nursery, digest fat badly. This fact has been emphasised recently by such eminent authorities as Still, Cameron & Osman.

Modern conditions of life make great demands on the nervous systems of such children. They are more highly strung, react more readily to emotional stimuli, and this strain is often reflected in digestive difficulties, such as cyclical vomiting, loss of appetite, constipation and bilious attacks.

It has been repeatedly demonstrated that these children cannot tolerate a diet rich in fat, and that whatever fats are to be dealt with must be metabolised in an excess of sugar. An insufficiency of sugar results in the production of ketone bodies and consequently ketosis. An excess of fat is split up in the bowels and neutralised by the valuable calcium and magnesium salts of the milk, which are subsequently excreted in the familiar pale, dry, and crumbling stools.

To meet the needs of this type of infant the manufacturers of "Cow & Gate" Milk Foods have provided a

HALF CREAM

PACKED IN A BLUE TIN

Cow & Gate Milk Food

PACKED IN A BLUE TIN

This food has the following composition:—

	Dry Food		Reconstituted (1 part in 8 parts of water)
Fat	15.5%	... ...	1.7%
Proteins	20.0%	... ...	2.2%
Lactose	58.0%	... ...	6.4%
Mineral Matter	4.5%	... ...	0.5%
Water	2.0%	... ...	89.2%
	100.0%		100.0%

Half Cream "Cow & Gate" has been used in the large class of "nervous dyspepsias" of infancy with eminently satisfactory results, proving invaluable as a food during periods of fat intolerance so noticeable in the "Jack Spratt" type of infant.

The makers will gladly supply samples and any further information, if required, and wish to remind Members of the Nursing and Medical Professions that the Cow & Gate Laboratories are always at their disposal for experimental work in connection with Milk Foods, and that they will be delighted to arrange visits to their factories in the West of England at any time.

Ephedrine in Asthma and Hay Fever

Ephedrine is an alkaloid isolated from Ma Huang. It has a pharmacological action less powerful than adrenalin but more prolonged.

The outstanding advantage of Ephedrine is that it can be given orally.

It is important that preparations of Ephedrine should be used that are made from genuine Ephedra (Ma Huang) and contain the natural alkaloid only.

BURROUGHS WELLCOME & Co.

Ephedrine Preparations

(1) Prepared from *genuine* Ephedra (Ma Huang).
(2) Contain only lævo-rotatory ephedrine.
(3) Contain no dextro-rotatory pseudo-ephedrine or other alkaloids which have relatively little activity.

For Oral or Hypodermic use:

'TABLOID' EPHEDRINE HYDROCHLORIDE

Gr. 1/4 (0·016 gm.)
Bottles of 25 *and* 100, *at* 1/1 *and* 3/3 *per bottle*

Gr. 1/2 (0·032 gm.)
Bottles of 25 *and* 100, *at* 1/10 *and* 6/- *per bottle*
Tubes of 6, *at* 8*d. per tube*

For Hypodermic Injection:

'HYPOLOID' EPHEDRINE HYDROCHLORIDE

0·03 gm. (gr. 1/2 approx.)
Boxes of 10, 1 *c.c. phials*, 3/- *per box*

For local application to the nose and pharynx:

'VAPOROLE' EPHEDRINE SPRAY COMPOUND

Bottles of 1 *fl. oz.*, 2/3 *per bottle*

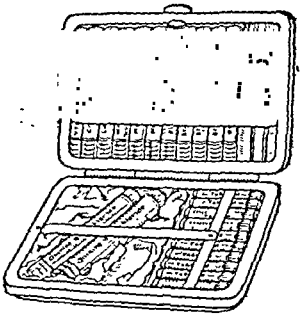
Hypodermic and Ophthalmic Cases

A wide range of hypodermic, ophthalmic and medicine cases may be inspected at the chief offices, Snow Hill Buildings, and at the Exhibition Rooms, 10, Henrietta Street, Cavendish Square, W.1. Some examples are here illustrated.

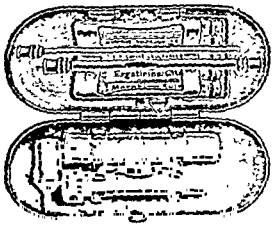


Measurements: 3¼ × 2½ × ¾ in.

TRADE MARK 'TABLOID' BRAND HYPODERMIC AND OPHTHALMIC POCKET-CASE

No. 80.—Contains 13 tubes of 'Tabloid' Hypodermic products, 10 tubes of 'Tabloid' Ophthalmic products, two camel-hair brushes, forceps, etc.

Aluminium ... ... 27/0 each



Measurements: 3½ × 2½ × 1 in.

TRADE MARK 'TABLOID' BRAND ASEPTIC HYPODERMIC POCKET-CASE

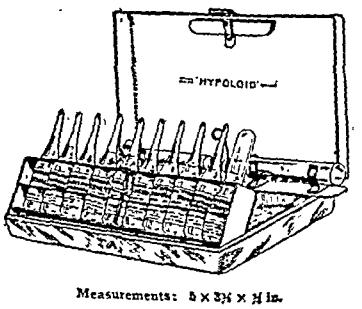
No. 40 (*"The Mussel Shell"*).—Contains an 'Agla' Aseptic Hypodermic Syringe, finger-grip, two steel needles, one exploring needle and five tubes of 'Tabloid' Hypodermic products.

Nickel-plated Metal, complete with soft leather cover, 20/0 each

TRADE MARK 'HYPOLOID' BRAND HYPODERMIC POCKET-CASE

No. 62.—Contains an 'Agla' Aseptic Hypodermic Syringe (min. 20 or 1 c.c.), two Rustless needles, 10 'Hypoloid' products, two files and a list of 'Hypoloid' products. ('Hypoloid' products may be specially selected if desired.)

Nickel-plated Metal ... 27/6 each



Measurements: 5 × 3¼ × ¾ in.

EDUCATIONAL NUMBER. SESSION 1929-30.

An Address

ON

MEDICAL EDUCATION AND LICENSURE IN THE UNITED STATES OF AMERICA.*

BY

SIR NORMAN WALKER, M.D., LL.D.,

DIRECT REPRESENTATIVE FOR SCOTLAND ON THE GENERAL MEDICAL COUNCIL.

My acquaintance with American medical education goes back a long way. When, after graduating in 1884, I proceeded to Vienna for post-graduate study, I made the acquaintance of quite a number of the 250 American graduates who were then studying there. There were 50 graduates of British schools, and it would be incorrect to say that we formed a high opinion of medical education in America from contact with some American colleagues in the practical classes. After five years, spent partly as a resident physician, and partly in general practice in Cumberland, I had, in 1890, my first opportunity of visiting the States, when I accompanied my father on a three months' tour. We landed in New York, made our way slowly across country to San Francisco by one route, and returned by another to Quebec, where we embarked for home. My father's interests were, of course, in the theological colleges, and, while he visited Princeton and Yale, I devoted much of my time to the medical schools in Boston, New York, Baltimore, Philadelphia, Chicago, Sioux City, Denver, San Francisco, Toronto, and Montreal. I look back over long years with a very lively sense of appreciation of the kindness of our American colleagues to a young man still well under 30. I made many friendships, most of them, alas! now broken by death. The closest was with Osler, whose guest I was in Baltimore, and with whom I maintained cordial relations to the end. It is something of a memory to me that it was to my ward that Osler paid his last visit to any hospital, less than a week before his death. Then, in 1906, when the British Medical Association held its Annual Meeting in Toronto, I again crossed the Atlantic, and, on the way home, spent a few days with my friend James C. Johnstone in New York, and got a pretty thorough insight into the workings of Cornell. My next visit was in 1920, when, on the invitation of the Carnegie Foundation, I accompanied Sir Humphry Rolleston, Sir Holburt Waring, and Drs. Des Maret and Roussy on a real American tour (of three weeks' duration) of selected universities in New York, Washington, New Orleans, St. Louis, Minneapolis, Chicago, Cleveland, Cincinnati, Ann Arbor, Boston, Philadelphia, and Baltimore. In spring of last year, on the invitation of the Council of Medical Education and Hospitals, a branch of the American Medical Association, I attended their annual conference, and took part in their debates. I may thus claim, I think, to have had rather exceptional opportunities of observing the development of medical education over more than forty years, and, being thoroughly convinced of the importance of the two great English-speaking nations understanding each other better, I feel it my duty to do what little I can to help towards this end. I accept to the full the following quotation from the *Chicago Daily News* (March, 1929): "Good relations between England and the U.S.A. depend on an informed, an impartial, and a critical public opinion."

* Delivered in Glasgow (Sir Donald MacAlister in the chair) and in Aberdeen (Professor Low, Dean of the Faculty of Medicine, in the chair).

BEGINNINGS OF MEDICINE IN THE U.S.A.

It is not possible to realize the present situation without knowing something of the development of medicine in the United States, and I am much indebted to an article by Professor Waite of Western Reserve University, Cleveland, on "The beginnings of medicine in the United States," for the material on which to frame this brief sketch.

The earliest doctors in the States, of course, had their education in Europe, and were graduates of well-known universities, but, as the supply of them was insufficient, the apprenticeship system, then in vogue in this country, was soon introduced. The apprentice was usually bound for seven years, on the mutual understanding that he was to serve his master, and his master was to teach him. When he had served his apprenticeship his teacher gave him a certificate of service and proficiency. This could be registered in a Court of Record, and its owner then became a legally qualified practitioner. Judgement of the proficiency of the apprentices rested solely with the teachers, and, so long as these latter were educated, competent, and appreciated their responsibility, the method worked well enough. Until 1765 there were no medical schools in the Colonies, and, as the number of qualified medical men immigrating bore less and less proportion to the population, the proportion of the apprentice type of doctor increased. Many of these had little proficiency either as scholars or teachers, and the training through apprenticeship steadily deteriorated. The seven-year term was shortened, and the quality of the training depreciated. "By the middle of the eighteenth century American medicine was decadent, a fact which was strikingly apparent in the medical service of the French and Indian war" (Waite). As early as 1735 medical societies began to appear, but these were local and transitory. In 1766 a State Medical Society was organized in New Jersey, and, in 1772, legislation was secured requiring examination and licensure by two judges of the Supreme Court, "with such assistance as they might call." In 1781 the Massachusetts Medical Society was incorporated; its charter empowered it "to examine all candidates for the practice of Physic and Surgery . . . respecting their skill in their profession . . . if found skilled in their profession, and fitted for the practice of it, they shall receive the approbation of the

Society in letters testimonial." The first licence was granted in 1782, the year in which Harvard Medical School was founded. Only the pupils of Fellows and Honorary Members of the Society were admitted to examination, and, in 1789, three years was prescribed as the minimum period of study, and there were enumerated among the studies necessary: Greek, Latin, the principles of geometry, and experimental philosophy. Other New England States followed, and an interesting feature of many of their charters was that they were obliged to describe and point out "such medical instruction or education as they shall judge requisite for the practice of physic and surgery." In other words, they laid down a course of study.

These State societies were, in a way, not unlike the chartered bodies of this country—the Colleges of Physicians and Surgeons, and the Society of Apothecaries. Like the colleges, they were particular about the persons whom they appointed to their governing boards, and they were equally particular about the qualifications of the candidates. They "vetted" the preceptors, and often refused to examine a candidate whose master was not, in their judgement, competent. This delegation of licensure to medical societies was extended and subdivided, so that, in some States, the licence was usually only valid within the political subdivision represented. When a licensee went elsewhere he had to procure a new licence.

About 1825 homœopathy and other sects began to appear; these formed their own medical societies, and, in some States, secured licensing privileges. In their zeal for propaganda it was charged that they lessened the requirements as to length of study under a preceptor, and were content with subscription to the tenets of their sect. The existence of these multiple sectarian medical societies aroused anxiety in the public mind, and, about 1835, legislation began to appear, taking the function of licensure away from the medical societies and placing it under a State Board of Medical Examiners appointed by the Governor. In some States the Governor's choice was restricted to a list of nominations by the medical societies. In many States the statutes stipulated that the Board should contain representatives of each of the several sects, but that no one sect should be in the majority. In their early days the State Boards accepted university degrees as sufficient grounds for licence, but the apprentices were examined; indeed, in comparatively recent years a few States admitted to their State Board examinations almost anybody. But the degree of M.D. was generally the accepted condition, and a definite commercial value came to be associated with it. And so things went on. In many centres the seriousness of the position was recognized, and excellent work was done in the endeavour to improve matters. But the time was not ripe; the necessity for reform had not yet been appreciated by either the public or the profession—things had got to get worse before they got better.

About 1880 came the orgy of organization of proprietary medical schools. In that year there were about 100 so-called medical schools. In 1890 there were 133, in 1900 there were 160, and the peak figure of 166 was reached in 1904. As at this date there were in the rest of the world 174, 47.5 of the total was obviously over-adequate, even for America.

It would be unfair to suggest that all the small medical schools were commercial undertakings. Not a few of them were bona-fide efforts of groups of doctors eager to do their share in the matter of medical education. But their means were insufficient; they could not equip laboratories as they needed to be equipped; they lacked, some of them, any hospital opportunities, and many of them, to their credit, committed suicide in the general interest.

These schools had apparently no difficulty in procuring State charters of incorporation. It is not an easy matter, in this country, to obtain a charter for the foundation of a university, but in those days, in America, the procedure seems to have been simplicity itself. Any State could, and apparently did, grant a charter to almost any group of applicants. There was no supervision of medical studies, and some of the chartered medical schools granted the degree of M.D. after a ludicrously short curriculum. Two sessions could be put into one year. But we must not be too superior. We did the same thing in my student days, when two summer sessions counted for a winter one, and the nominal four years could be done in a little over three years. Under these conditions an amazing number of schools were established. There are records of no fewer than 447, but fortunately they did not all exist at one time, and the careers of many were very brief. As an instance that it is still easy to procure a charter, I take these facts from an official publication of the American Medical Association, February 15th, 1928: "The American Medical University is the successor of the Kansas City College, which was shown to be involved in a diploma mill scandal 1923–25, and its charter was revoked on June 23rd, 1926. The successor got a new charter, and started on its new career on August 9th, 1926."

It then became necessary to repeat the procedure of a century earlier, when medical societies were forced to examine the certified pupils of careless and incompetent preceptors, as a precaution against inefficient training. In the last decades of the nineteenth century, as a precaution against the inefficiency of weak schools, all medical school graduates, as well as those educated under preceptors, were compelled to take the examinations of the State Board of Licensure, and automatic licensure on the diploma was terminated.

The examination of the State Boards was a formidable thing, on paper. It comprised all the subjects of the medical curriculum, and involved some three days spent in answering written papers on these, and was therefore, theoretically, a very severe ordeal. There was no clinical examination. A, to us, curious regulation provided that no examiner on a State Board should be a teacher. The object of this regulation was to prevent a professor in a proprietary school deriving pecuniary advantage from his position of examiner. It is necessary at this stage, in order to make the position clear, to point out the root differences between American methods and ours.

In this country there are twenty-three licensing bodies, whose degrees or diplomas confer on their holder the right of entry to the *Medical Register*. These twenty-three bodies carry out their work under the supervision of the General Medical Council, whose duty it is to certify to the Privy Council that the degrees and diplomas issued are conferred after a course of study and examinations which ensure that their holders have a "sufficient" knowledge of medicine, surgery, and midwifery to enable them to practise medicine "efficiently." The Council gathers the information to enable it to pronounce on the efficiency of the study and examinations by requiring regular returns from all the bodies annually, and by an organized system of inspection and visitation, which is more or less continuously going on. In case of misunderstanding on the other side, it is advisable to be a little more explicit. Of the twenty-three licensing bodies, eight—the three Colleges of Physicians, the Colleges of Surgeons of England and Edinburgh, the Faculty of Physicians and Surgeons of Glasgow, and the Society of Apothecaries and the Apothecaries' Hall, Dublin—are only examining bodies, and do not officially control schools of medicine. The Royal College of Surgeons in Ireland does. On the other hand, there fall to be added the twelve medical schools attached to London hospitals, the three extramural schools in Edinburgh and Glasgow, University College, Dundee (St. Andrews University), and the University Colleges of Cork and Galway (National University), making a total of thirty-three medical schools. As the population of the two countries is about 2.6 to 1, we seem to be almost equally supplied with medical schools.

In the United States quite another system is in operation. There are to-day eighty medical colleges (ten of these only give the first two years of instruction) in the U.S.A., and the degree of none of them carries with it any right to practise or of admission to any official medical register. There is no General Medical Council, and the laws regulating medical practice may vary from State to State. The doctrine of State rights requires every State to lay down its own conditions and regulations for the practice of medicine (or the healing art). Each State has at least one medical licensing board, and, in theory, every-

examination. You will notice that I said at least one medical board, and here lies one of the great differences in medical practice in the two countries. In this country there is no prohibition of medical practice by the unqualified, though there is in the branches of midwifery, dentistry, and venereal diseases. In all the United States there are strict laws prohibiting practice by those who are not somehow officially licensed. There are some who wish we had similar laws in this country, and at one time I was disposed to share that view. A larger experience has shaken that disposition. If, in this country, any crank wishes to practise his own theories, he is free to do so at his own risk, and those who employ him do so at theirs. All the law does is to provide a list—the *Medical Register*—of those who are qualified practitioners. And yet I do not believe there is any country in the world which contains a less proportion of irregular practitioners than ours.

Let us see how the other plan works: I take for the purpose the State of Connecticut, an old-established Eastern State. My information is that there are at least six (probably seven) separate boards of examiners whose licence enables the individual to practise medicine in some form. The Regular (formerly incorrectly called Allopath) Board, the Homœopathic Board, the Eclectic Board, the Osteopathic Board, and separate boards for chiropractic, naturopathy, and drugless healing. It is to be noted that the only branch of medicine—if one may call it so—which can be practised by anyone, anywhere, without any licence, is Christian Science. Each licensee must, in theory, restrict himself to the methods of his sect—for example, a drugless healer who is proved to have made use of any active drug is liable to fine or imprisonment. The index to the *Bulletin* of the Federation of State Boards contains pages of records of such convictions.

I have it on excellent authority that it may be taken that, throughout the States generally, there is one such irregular practitioner to every five regular ones. The education of many of the irregular practitioners leaves much to be desired, and several States, concerned about the situation, have endeavoured to correct it by the introduction of what is called a Basic Science Law, which requires every applicant who desires to practise any branch of the "healing art" to pass an examination in anatomy, physiology, pathology, bacteriology, and diagnosis, after satisfying the Basic Science Board that they have had an education of some sort in these subjects; physics, chemistry, and biology are not covered by the requirements of the examination. Pharmacology is never included, because of homœopathic, chiropractic, drugless healing, and other such doctrines. The aim of the Basic Science Law is to ensure some common standard of knowledge of the underlying medical sciences, common to all branches of the healing art, and they are proposed mostly for States which have several boards of examiners. They are also intended to keep hopelessly irregular practitioners out.

The Basic Science Laws are not looked on with favour by the earnest medical reformers; they give permanent and legal recognition to sub-standard cults, and they impose an undue extra burden on the graduates of Class A schools, who have already passed their examinations in these subjects, and who form 96 per cent. of the successful candidates at State Board examinations. They tend to wreck the working system of reciprocity which existed between many States, and it is a little curious that the free trade—using the word in its ordinary sense—which exists between all the States of the Union, and makes them the largest free trade area in the world, is conspicuously absent in medicine.

It is, however, interesting to learn that the number of cult schools grows steadily less. This is shown in the following table, which gives the numbers of certain such schools in 1920 and 1927 respectively.

	In 1920.	In 1927.
Schools of osteopathy	13	8
Schools of chiropractic	79	40
Schools of naturopathy	20	12

The number of students in the schools of chiropractic has declined notably in the last five or six years.

The Federation of State Boards has recently performed a remarkably courageous action: the Board has done admirable service in the past by prescribing a rather cast-iron curriculum, which has served its day and generation. In the spring of this year it decided to discontinue prescription of a curriculum, and to turn the responsibility of this over to the medical schools, to whom it properly belongs. The standard will be under the direction of the Association of American Medical Colleges, all the members of which are Class A schools.

Early in this century there came a stirring. It is not for me to distribute bouquets; obviously, many minds were thinking in the same direction, and the movement was general. The active spirits of the American Medical Association, of the Association of American Medical Colleges, and of the Federation of State Medical Boards were all thinking hard, and seeking a solution of their problems. They were sapping and mining for an advance.

REFORM.

In 1907 the Council of Medical Education of the American Medical Association made its first official inspection of all the (then 160) medical schools in the U.S.A. The report presented in that year is very interesting reading. It was made by Dr. A. Dean Bevan, and the contrast between it and the corresponding report which I had the pleasure of hearing from the lips of the same man in February, 1928, was quite arresting. It is not given to many reformers to see their labours so fruitfully fulfilled. Dr. Bevan has this year resigned the post, and passed on his chairmanship to Dr. Ray Lyman Wilbur, president of Stanford University. That the choice is a good one is surely emphasized by the fact that President Hoover has appointed Dr. Wilbur Secretary of the Interior in his Cabinet. The Council has been further fortunate in having had as its secretary since 1907 Dr. N. P. Colwell, who can and does answer any question on medical education in the States by return of post or by telegram. A third to whom I am likewise much indebted is Dr. Walter L. Bierring, Hon. M.R.C.P.Ed., who has filled, during all these strenuous years, the important positions of secretary and treasurer of the Federation of State Boards, and editor of the Federation *Bulletin*. It gives me great pleasure to have this opportunity of publicly expressing my indebtedness to these friends.

Continuing my metaphor, it may, I think, justly be said that the blasting powder and the detonator were supplied by Flexner's famous report—*Bulletin* No. 4 of the Carnegie Foundation for the Advancement of Teaching, published in 1910. It gave a mercilessly candid report of the condition of the 140 medical schools then existing in the U.S.A., of which the following will serve as a sample:

"*Entrance Requirement:* Nominal.

"*Attendance:* 9, of which 7 are from x.

"*Teaching Staff:* 27, of whom 26 are professors.

"*Resources Available for Maintenance:* Fees amounting to 1,060 dollars (estimated). £210.

"*Laboratory Facilities:* The School occupies a few neglected rooms on the second floor of a fifty-foot frame building. Its so-called equipment is dirty and disorderly beyond description. Its outfit in Anatomy consists of a small box of bones, and the dried-up fragments of a single cadaver. A few bottles of reagents constitute the Chemical Laboratory. A cold and rusty incubator, a single microscope, and a few unlabelled wet specimens, etc., form the so-called equipment for Pathology and Bacteriology.

"*Clinical Facilities:* There is no dispensary and no access to the County Hospital.

"The School is a disgrace to the State whose laws permit its existence."

And yet the degree conferred was legally as useful as that of Harvard.

GRADING.

The American Medical Association.

It is difficult for us, used for seventy years to our own statutory General Council of Medical Education and Registration, to realize all that has been done in the U.S.A. by a purely voluntary association. It could not have been done in this country. Now and again, with us, a daring journalist publishes statements which he knows may be the subject of legal proceedings. The American Medical Association seems to be doing this all the time, and one can only surmise that the laws of libel in our two

countries are not the same. Listen to this from a speech by Dr. Bevan:

"I remember as well as though it were yesterday, although it was twenty-two years ago, that, when I presented these tables, I said: 'It is evident from a study of the medical schools of this country, and their work, that there are four especially rotten spots which are responsible for most of the bad medical instruction. They are: Illinois with fifteen medical schools, Maryland with eight medical schools, Kentucky with seven medical schools, Tennessee with ten medical schools.'"

In 1906 the American Medical Association took the matter seriously in hand, and in 1907 issued its first list of the existing 160 medical schools, graded alphabetically.

The method of grading took into consideration the following ten points:

1. Showing of graduates before State Board examinations.
2. Requirements and enforcement of satisfactory preliminary education.
3. Character and extent of college curriculum.
4. Medical school buildings.
5. Laboratory facilities and instruction.
6. Dispensary facilities and instruction.
7. Hospital facilities and instruction.
8. Extent to which the first two years are officered by men devoting entire time to teaching, and evidences of original research work.
9. Extent to which the school is conducted for the profit of the Faculty, directly or indirectly, rather than teaching.
10. Libraries, museums, charts, etc.

For each of these ten marks were allotted.

Class A schools, "in good standing," comprised those whose marks were 90–100; Class B, 80–90; C, 70–80; D and E, 50–70; and F, 50 and below.

Classes A, B, and C, totalling 81, obtained over 70 per cent., and were recommended to the State Boards as being "up to standard." Classes D and E, totalling 47, were informed that certain improvements might bring them up to the 70 mark. Class F (32) was apparently beyond redemption. The effects were soon apparent. In 1910 the numbers had dropped from 162 to 131, in 1915 to 96, in 1920 to 85, and in 1925 to 80, at which the figure remains to-day. In 1913 there were graduates from Class A schools numbering 2,539, from Class B schools numbering 1,050, and from Class C schools numbering 392. In 1927 the corresponding figures were 3,798, 117, and 120; and in 1928 they were 4,091, 96, and 75. There are now seventy-two schools in Class A, three in Class B, and five in Class C, but these last are no longer given general recognition by the American Medical Association.

The Council of Medical Education and Hospitals appoints inspectors to "visit" each of these schools, and, on their report, grades the schools annually. A Class A school may, for example, be warned that, unless this or that improvement is made in its arrangements before the next inspection, it will be put in Class B, while a Class B school may be given the hope that, if certain improvements are made, it may mean promotion. The system works very smoothly, and degradation is, to-day, rare.

Before I leave the subject of inspection, the following quotation from Dr. Bevan's address, which I had the pleasure of listening to in February last in Chicago, will be of interest, as showing the spirit in which inspection is offered and taken.

"When we began our first inspection there were seven medical colleges in Louisville, Ky. I received a letter from one of my good friends in Louisville one day, telling me not to come to Louisville, because all the medical schools had agreed not to allow themselves to be inspected by the Council. I wired at once that Dr. Colwell and I were leaving for Louisville that night, and desired to inspect the schools the next day. With true Southern hospitality, they received us, and gave us every opportunity to inspect their schools. They gave us a luncheon at the Pendennis Club. We discussed the subject of consolidating all the medical schools in Louisville into one strong school, which might then secure the united support of the medical profession and the citizens of Louisville, and secure the use of the Louisville Hospital as a hospital for teaching and research; this was finally agreed to and finally carried into effect, so that, to-day, Louisville has a single school much stronger than any of its predecessors, and enjoys the benefit of excellent clinical material. The same story was repeated in many cities of the country."

I think you will agree that the following quotation from an address delivered in October, 1928, by William Lowe Bryan, president of Indiana University, is more trenchant than my modest criticisms.

"An extreme illustration of this, as you know, is to be found in the history of medical education within the past twenty-five years. Something more than twenty-five years ago you saw scores of fraudulent schools, and other scores of schools unforgivably weak, and unable to give proper training for medical practice. You saw the central duty of bringing medical science at its best to the people through rightly trained physicians. You went to war. You inspected schools with relentless thoroughness. You published the worst you found there without mercy. You agreed upon ironclad prescriptions. And then you made lists. The lists did the work. Your black list killed the weak and the fraudulent schools by the score. Within an astonishingly short time you have wrought a revolution in medical education in America, great, and, as we believe, necessary and inevitable."

American educational methods differ so much from ours that it is well to give a brief account of them. There seems to be a general opinion that, take it all round, our primary and secondary school education is rather better than that of the United States; whether, as some assert, this is influenced by the lesser proportion of male teachers in America must be a matter of opinion. The same system of inspection and grading by bodies, not all of which have official authority, extends to the schools, and only candidates from "approved" schools are accepted by the colleges. The requirements of the medical schools have steadily risen. Only a few years ago one year of "college" training sufficed for entry to Grade A medical schools, but for long there had been a movement towards a wider general education. Johns Hopkins began as far back as 1893. Its directors gripped the principle that an adequate general education was the only sure foundation for a sound medical education, and they limited their admissions to those candidates who had had two years of college education. Harvard followed in 1900, Western Reserve in 1901, Rush in 1903, and California in 1905. Then the rate quickened up, and now a two years' college course is a condition of entry to all Class A schools, while a three years' college course, which usually means a degree in arts or science, is a condition of entrance to fourteen medical schools. One of them requires four. This takes our thoughts back to the days when many Scottish students took the old three or four years' course for the M.A. before commencing to study medicine.

At college the student studies biology, chemistry, physics, English, another language (French or German), and mathematics. Some colleges include psychology and sociology in the course.

The next thing a student has to do is to gain admission to a medical school. Most of the American schools now limit their entry to the number that they are satisfied they can efficiently teach. For example, the Western Reserve (Cleveland) medical school had more than a thousand applications in 1927; only 122 were accepted. Of these, 55 held either the B.A. or B.Sc. degree, and one was a Ph.D.

Some staggering figures are given as to the number of applicants, but, like all statistics, these have to be carefully analysed. Knowing the difficulties of gaining admission, the astute applicant does not confine his application to one school. It is apparently common to apply to five or six; one applicant is reported to have put in forty applications—all unsuccessful! This difficulty of admission makes some anxious lest the supply of doctors should become insufficient; but when the figures are analysed—and analysis of figures is a strong point in America—it is seen that the number of rejections is not so very serious. In the academic year 1927–28 23,590 applications were received by the eighty medical schools. Lest you should find this statement incredible, I hasten to add that these applications were made by only 11,282 individuals. Of these, in round figures, 6,500 were accepted (96 per cent. by Class A schools) and 4,500 refused. As some were accepted by more than one of the schools to which they had applied, the actual number of students commencing the study of medicine was materially less than the acceptance figure of 6,500. In 1928–29 the figures were: applications 29,166, applicants 12,537, accepted 7,014, refused 5,523. In 1928 there were 1,363 students registered in England,

Scotland, and Ireland. A table appended to the report of the Education Committee of the General Medical Council for 1928 shows that about a quarter of the practitioners registered in 1927 had not been registered as students, and, assuming a similar proportion of our existing students are not registered, we should arrive at a figure of nearly 1,700. There are, therefore, three and three-quarter times as many entrants in the United States as in this country, and the population is roughly 2.6 to 1.

Having obtained admission to the medical department of a university, the student, under the name of "Freshman," commences the study of medicine proper with anatomy and physiology. As a "Sophomore" he continues these studies in his second year, and, in addition, commences the study of bacteriology, pathology, and pharmacology—the laboratory subjects. It is the general rule that, during these two years, the student does no clinical work, but a tendency (described as infiltration) to introduce this earlier is growing, and short courses, very well organized, are established to relate these fundamental subjects to medicine and surgery. Other schools are extending the laboratory courses into the third and fourth years. Some regard the early approach to clinical work with misgiving. "It is becoming more difficult to secure instructors who have the proper idea as to medical education. Many do not appreciate the relative importance of their special subjects, nor the reasons why these have been included in the curriculum."

In his third year, under the designation of "Junior," the student usually begins clinical work, and this and the next year are devoted to a very highly organized—possibly too highly organized—scheme of study.

Here I digress to say something about the examination system of the American universities. Our students might receive, at first with jubilation, the news that there are in America no professional examinations like ours, where a stranger sits on the other side of the table with their professor, and there is even a chance of a "visitor" from the General Medical Council dropping in to listen. But let them not be too envious. Americans aim at something quite different from our system: an elaborate system of card indexing keeps the student's work constantly under the eye of his teacher; class examinations are frequent, and a final or terminal examination is held by the professor and his staff at the end of each year. Not much patience is shown with the slacker, and there are no "chronics" in up-to-date American universities. If a student's work has not been satisfactory he receives a warning, and if his work in the subsequent term does not show marked improvement he is "honourably dismissed." In the old days, when there were 160 odd schools available, this was perhaps not a very serious matter, as he could go to another school. But now that nearly all the schools are Grade A, and all practise this same plan, and as the intercommunication between universities regarding students is carried to the "nth" degree, it has become a very serious matter to be dismissed. There is some apprehension lest a few of those students who have recently applied for admission to British universities may be of this category.

The examinations are thus intra-university affairs, and the system of having an external examiner, which is general in this country, is not in evidence in the United States. One reason for this is that a degree carries with it no right of registration, as we call it in this country, or licensure, as it is called in the States. The candidate who desires to practise in a particular State has to make application to the State Medical Board, the only body which can give him the right to practise. These make their own conditions, and there is a growing tendency—a rapidly growing tendency—to require that each applicant for admission to the State examination must have not only a degree from an approved university, but evidence of having served for one year as an "intern." The "intern" year is an interesting recent development in American medical education. The credit for introducing it belongs to the State of Pennsylvania, whose State Medical Board made it a condition of licence in 1909. The University of Minnesota made it a condition of graduation in 1910. Eleven colleges now require it before they confer their degree, and fourteen States make it a condition of licensure.

We are, of course, familiar with the fact that most of our graduates realize the value of a period of residence in a hospital, and the competition for these posts is keen. But it is commonly urged that it would be impossible to introduce the American plan in this country owing to the relatively small number of such posts. Similar arguments were, I have no doubt, advanced in America, but the experiment was made, and it is now recorded that, of the graduates of last year, about 95 per cent. had held posts as "interns." It is not only that there is a large number of hospitals in America, but they, too, fall under the grading system. A special committee of the American Medical Association grades the hospitals, and as one of the conditions required for the upper grades is that there must be a definite proportion of "interns," this apparent difficulty melts away. The post is not quite the same as that of our house-physicians or surgeons, but generally that of an assistant house-physician or surgeon, or a resident clinical clerk, while some universities accept a year's work in a laboratory as equivalent. That there is room in this country for more residents, and, not least, in our smaller hospitals, hardly requires argument, and I for one should like to see the benefit reaped by the American hospitals, and the American public, who are thereby provided with better trained doctors, extended in this country. Adding all these requirements together, it will be seen that the average American doctor has to go through a seven years' curriculum: two in a college doing the pre-medical subjects, four in a medical school, and one as a resident in a hospital. It is little wonder that his age on graduation is about 27.

This prolonged curriculum is giving rise to some apprehension that it may discourage suitable candidates from studying medicine, and there is considerable uneasiness lest the desire to improve medical education should lead in a direction which may not be in the public interest. There are apprehensions that the improved and prolonged education now demanded may bring the supply of doctors below the public demand for medical service—especially in rural areas. It is true that, in the States, as in other industrial countries, the move from country to town affects also the doctors, and that many villages, which used to have a resident doctor, no longer have one. But there are compensations: the telephone, the motor car, and the excellent roads so increasingly numerous, bring doctor and patient nearer together; ten miles in a buggy is much more than twenty-five miles in a car, and the telephone, by taking the place of the messenger, cuts a big slice off the time the doctor takes to reach the patient. And if, added to these advantages, the doctor is more capable, better trained than his predecessor, surely the advantages of the changes outweigh the disadvantages. This uneasiness is voiced by one of the best known and most respected of American teachers, William J. Mayo, who, in an article entitled "The aim and ideals of the American Medical Association" (*Proceedings of the Mayo Clinic*, July 11th, 1928), directs attention to the fact that the average age of graduation in medicine in the U.S.A. is around twenty-seven years, and that consequently many bright men are being drawn into other professions. He makes some flattering comparisons with the graduates of Edinburgh, where the average age at graduation is about three years less, and he makes two suggestions which I give in his own words:

> "I do not advocate a letting down of standards in our medical schools, but I am convinced that one year of time could be saved in our grammar schools, and a year could be saved in our medical schools by the Four Quarter System. That children in the growing age have three months' vacation in the summer is no reason that young men and women, at the height of their physical vigour, in a world on a twelve-months' working basis, should have three months' vacation."

Under the Four Quarter System the work of any three consecutive quarters constitutes a college year. This would not be permissible under the laws of seventeen States, including New York and Pennsylvania, but the opinion is expressed in the *Federation Bulletin* that, eventually, all

State laws may be so modified as to permit medical students to save this year of valuable time, if they are physically and educationally fit to do so. This is surely significant of a trend in this direction.

In some schools classes go on continuously, a procedure which is facilitated by the very large staffs attached to all the departments. A student can thus put in the requisite number of terms in three years. It is not a method which commends itself to me. I do think, and I have often said, that the holidays which our senior students get are too long, but to expect a man to work at high pressure for three years, with only a month off in each, seems a severe tax on his physique, mental and bodily. Further, I think all experienced teachers will agree that the longer the period over which a subject is studied, the more likely is it to make a lasting mark upon the student's mind. I think, however, we might very well consider the American plan, in so far as it makes teaching, and particularly hospital teaching, available all the year round. It seems to an outsider that it is the strictness of entry, an excellent thing in many ways, which is responsible for the length of the American curriculum. The most recent modification of the Four Quarter System is more merciful. Under it each calendar year is divided into four terms of eleven weeks each, thus leaving eight weeks in the year for vacation.

The National Board.

Even the most superficial student of American politics must make himself acquainted with the democratic doctrine of State rights. In certain matters—and the practice of medicine is one of these—every State is a sovereign authority, and can make any laws it likes. For example: a practitioner licensed to practise in New York is acting illegally if he practises (without a New Jersey licence) in New Jersey, just across the river, and so all over the country. A would-be practitioner must be licensed by the Board of the State in which he wishes to practise.

The drawbacks were recognized and deplored, but the very idea of Federal interference is abhorrent to the State right diehard. Between some States there was established a plan of reciprocity under which each recognized the other's licence; but there was no general arrangement, and some States sternly maintained that it was the duty of each State to satisfy *itself* of the fitness of a medical practitioner to treat *its citizens*. And I have described to you the pretty job they made of it. As the population of the States grew, as communications multiplied, and as the American is more migratory in his habits than any other race, the inconveniences were more and more realized, but the solution was long delayed for America. In 1915 the late Dr. W. L. Rodman of Philadelphia, then President of the American Medical Association, launched the movement which culminated in the establishment of "The National Board of Medical Examiners of the United States," one of the most interesting recent developments in connexion with medicine in the States. The fact that the State Board examinations only give practice rights within their own boundaries, the fact that teachers of any medical subject were specifically excluded from membership of the examining boards, and the fact that candidates were examined (in perhaps three days) in every branch of medicine, directed the attention of those who were looking for improvements to a possible better way. The Board began its operations in 1916 with the purpose of establishing "a standard, qualifying examination, which could be safely accepted by all State Boards of Medical Licensure as an adequate qualification." It was chartered in 1922, under the laws of the District of Columbia. It is an unofficial body, and yet has a semi-official aspect, for the Surgeons-General of the three public services—Public Health, Army, and Navy—not only are members, but each carries with him to the Board an assessor. Among the other fifteen members of the Board, who are chosen by a method of co-option, there are at present two professors of medicine, two of surgery, and two of obstetrics, and one each of biological chemistry, physiology, and pathology. The remaining members are connected either with a university or with the Federation of State Medical Boards.

When Sir Humphry Rolleston, Sir Holburt Waring, and I visited this examination in Philadelphia in 1920, the old traditions of the State Licensing Board examination still lingered, and candidates were examined, in less than a week, in all the subjects of the medical curriculum. Partly, we like to think, owing to our friendly criticism, a better method now exists. The student who has successfully completed the first two years of work in a Class A medical school may then sit for Part 1 of the examination, which includes anatomy, physiology, physiological chemistry, general pathology, bacteriology, and materia medica and pharmacology. Part 2 of the examination, which consists of medicine, surgery, obstetrics, and medical jurisprudence, is taken at the end of the fourth year; and Part 3, clinical medicine and its branches, clinical surgery and its branches, obstetrics and gynaecology, and public health, is taken after the candidate has rendered satisfactory service as "intern" for one year in an accepted hospital or laboratory. The Board holds examinations for Parts 1 and 2 simultaneously in all Class A schools of the United States, provided five candidates are forthcoming, and the examination in Part 3 is held in eighteen different medical centres, so selected as to be reasonably accessible to all candidates. The figure laid down as the pass mark in these examinations is, to our ideas, placed fantastically high at 75 per cent. of the marks of each part of the examination, and a mark below 60 per cent. in any one subject involves failure. Having had the good fortune to be present on one occasion when the marks were considered, I can testify to the care with which they are estimated. And every examiner knows that it does not matter very much what numerical figure is put on the pass mark.

The fees for admission to the examinations seem to be based on Old rather than on New World standards: the registration fee is $5, the fee for Part 1 $10, for Part 2 $15, and for Part 3, which carries with it the diploma, $45, making a total of $75—about £15 15s.

So successfully has the plan been received that the National Board's certificate is now recognized by the licensing authorities of thirty-seven States and Territories, and the medical boards of most of the remaining plan to recognize the National Board as soon as their laws can be suitably amended. The Board's certificate is accepted by the U.S. Army and U.S. Public Health Services as the scientific qualification for admission to the medical corps of each of these services. Admission to the Navy is determined by an annual competitive examination. The diploma is becoming increasingly popular in the States. In 1922 only 20 passed; in the year 1927, 450 passed Part 1, 315 Part 2, and 270 Part 3, and obtained the diploma.

This recognition is not confined to the United States: diplomates of the National Board are admitted to the final examinations of the English Conjoint and the Scottish Triple Qualification Boards, and, in return, the National Board admits to Part 3, its final examination, the diplomates of these boards. It is interesting to learn that the Spanish authorities now admit diplomates of the National Board directly to their revalidating examination.

The privilege of admission to the final examination is not at present directly available to our university graduates. There is, however, a way round for those of them who may desire to practise in the States. The three Scottish medical corporations, when they combined to give the triple qualification, surrendered all claims for the recognition of their single licences as admitting to the *Medical Register*. They retained, however, their right to confer them on any suitable candidate whose name was already on the *Medical Register*. Thus, one of your graduates who desires to practise in the United States will be well advised to add to the letters M.B., Ch.B., the L.R.C.P., L.R.C.S., or L.R.F.P.S.

The advantages enjoyed by the diplomates of the National Board have stimulated other forms of effort to achieve the same end. When there were 167 schools, each its own judge of its own merits, the State Boards already mentioned examined everyone who desired to practise within their confines. Now that the standing of all the regular medical schools can be easily ascertained, a practitioner who is a graduate of a good school, and is licensed in his own State, can get a licence in a second State by having his credentials "endorsed" by the second State, without examination. For the man who is satisfied with

one move—and most of us are—this endorsement suffices; to the more restless spirits, and there are a good many of them in America, the roving commission of the National Board, which runs in thirty-seven States, makes a stronger appeal.

This seems an appropriate place at which to quote from the address of Dr. Platter, President of the Federation of State Boards, delivered in February of this year.

"Legislation is an American disease. Our greatest fault lies in strenuous efforts for new legislation, which is supposed to work automatically to relieve or cure a bad situation.

"I have an opinion that we are at the parting of the ways; either we must present a united front with a carefully considered and thought-out programme for general enforcement, or . . . we should quit deluding ourselves and fooling the public and profession, and embrace the British system of licensure. For the present, I prefer to be enrolled in the first group; we should have a Medical Practice Act Model capable of universal adoption . . . it will take perhaps five years to determine the results to be obtained by such procedure. If, at the end of that time, substantial progress has not been made, then I should unhesitatingly recommend that we busy ourselves with the improvement in medical education, and endeavour to have legal recognition given only to those holding proper educational qualifications, and permit the unprepared, the fakir, and the charlatan to practise to their heart's content, restricting them only in that they will have no legal recognition. These are the problems which I believe concern us. I offer you two solutions. The first is in line with the duties imposed upon us when laws creating Boards of Licensure were enacted, and may be characterized as the American 'ideal.' The second closely follows the British system, and may be characterized as 'practical.'"

Not the least difficult part of an address such as this is its conclusion. I have given you a rapid survey of the position in the United States, and from it you can appreciate the differences in methods. Last year, in Chicago, it was suggested to me that I might draw a comparison between the methods of our two countries. I declined then, and I do not propose to do it now. In February, 1928, I described our methods to an American audience and left it to draw its own conclusions; to-day I have endeavoured, to the best of my ability, to describe them to you, and I commend them to your very careful study. There is much that is good in the methods of both countries, and each can learn much from each other. There are some who think that our American friends are too fond of experiments, and suggest that they too often pull up the seedlings to see how they are getting on. Well, perhaps it is true that the Americans, as a nation, are more ready to make experiments than those of older civilizations, but, after all, this is the privilege of youth, and the less adventurous may derive much benefit from the ventures of the more daring. Co-ordination, co-operation, unification, simplification, rationalization, are the slogans of industry to-day, and they have undoubtedly influenced the reform of medical education in the States. There is a freedom in, and there are opportunities for, discussion which are less frequent here. Every year those interested meet in Chicago for three days to exchange views and discuss new proposals. One evening last February I had the pleasure and interest of dining with the deans of twenty-three medical schools, who had come from all over the States, and Canada. I commend the example to our deans.

When, a few minutes ago, I made a passing reference to the prophet Ezekiel, I was conscious that some of you might scent something of a fallacy. I refer the doubters to their Bibles. In the valley of Ezekiel's vision the bones were very many, like the American schools of medicine in 1900, and they were, metaphorically, very dry. Following Ezekiel's first prophecy, which may be compared with the various reports, there came a noise and a shaking, and the bones came together bone to bone, and then the sinews attached themselves to their proper origins and insertions; later, the flesh came upon them; and last, the skin covered them. "But there was no breath in them." An unfriendly critic might overdo that point, and say that the American schools are too uniform, show too much evidence of mass production, and are too mechanical. But Ezekiel had a second prophecy: he prophesied unto the wind, *and the breath came into them.* There is ample evidence to-day that the breath of freedom is stirring in American medical schools. They are striving for the freedom to try, each in its own way, other methods, some of them new, and some of them old. It will stimulate a healthy upward competition among their schools, all or almost all of them to-day excellent, towards yet higher levels.

THE PLACE OF HUMAN PHYSIOLOGY IN THE TRAINING OF MEDICAL STUDENTS.*

BY

FRANCIS R. FRASER, M.D., F.R.C.P.,

DIRECTOR, MEDICAL PROFESSORIAL UNIT, ST. BARTHOLOMEW'S HOSPITAL; PROFESSOR OF MEDICINE, UNIVERSITY OF LONDON.

THE MEANING OF HUMAN PHYSIOLOGY.

In a lecture delivered before the Harvey Society in New York in 1916 Professor J. S. Haldane of Oxford said: "Medicine needs a new physiology which will teach what health really means, and how it maintains itself under the ordinarily varying conditions of the environment." It would be difficult to frame a better explanation than this of what is meant by human physiology; and the selection of this subject for discussion indicates that a serious attempt has been made to provide such a new physiology.

For half a century before that date physiology had been progressing actively, stimulated by the desire to account for activities of living organs in terms of physics and chemistry. Great strides were made in demonstrating the functions of organs, in determining the mechanism of their action, and in analysing the mechanism in terms of physics and chemistry. These advances in what may be termed "analytical physiology" were the result of experiments on isolated animal organs, by means of which the variables could be eliminated and causal factors studied under carefully controlled conditions. Their effect was to indicate the possible functions of an organ and the causes of its activities. The probable functions of human organs and the probable causes of the activities of these organs in the living body were then deduced. To take a few simple examples: the capacity of such an organ as a salivary gland to secrete a juice of importance in digestion was demonstrated, the conditions of its blood supply necessary for successful secretion were defined, stimuli capable of causing this secretion were discovered, and it was shown that these acted through the nervous system. It was inferred from observations in the human being that the human salivary glands secreted their juices in response to similar stimuli and for a like purpose. The contractions of muscles were shown to be the result of certain stimuli conducted to the muscles by nerves, the physical and chemical phenomena coincident with the activities of the muscles and nerves were seen to be essential, the energy requirements of these experiments were quantitated, and their sources defined. The order of events in the beat of the heart was elucidated, and the dependence of each event on those preceding was demonstrated. The paths of excretion of the waste products were discovered. The characters of the blood, and the variations found in healthy individuals, were defined.

The new phase in thought and in investigation in physiology turns on the meaning and implications of "normal." The human body is exposed to the ever-varying conditions of the environment, and is constantly adjusting itself to them. So long as it maintains its

* Read in opening a discussion in the Section of Physiology and Biochemistry at the Annual Meeting of the British Medical Association, Manchester, 1929.

efficiency under these varying conditions and adjustments it is considered to be in health and to be normal. Health and normality are not therefore strictly definable, but indicate a wide range of bodily activity. Within this range no single organ maintains a fixed and rigid condition, but is constantly active to maintain its part in the functioning whole and constantly altering its activities in co-operation with the other organs of the body in response to the ever-changing conditions imposed from without by the environment. Certain features of the body seem to be relatively constant within the limits of health, while others show more variability. The body temperature, the hydrogen-ion concentration and salt concentration of the blood are relatively fixed. The frequency of the heart beat, the respiratory activity, and the composition of the urine vary to a much greater extent. The older physiology told us little of how in the ever-changing conditions of human life these relative constants are maintained, and of how the various organs of the body co-operate to effect this. It told us much of the possibilities of the organs to act in this way, and how these activities can be brought into play. It has given the clues for the newer physiology, for human physiology, for the study of the human body in health; and so for the recognition of the points at which these adjustments may fail. When they fail, inefficiency results and symptoms appear. As an example of this conception I should like to quote an experiment that brought home to me the range of adjustment compatible with health and the ultimate appearance of symptoms under excessive stress.

We had the opportunity of making careful observations on a healthy man of the effects of the administration of an acid in the form of ammonium chloride. By increased breathing, by increased urinary output, and at the expense of a lowering of the carbon dioxide carrying power of the blood, adjustment was at first successful in maintaining apparently healthy conditions. With an increase in the dose of ammonium chloride, however, the adjustments failed to maintain efficiency, and symptoms appeared. The increased breathing became such that dyspnoea resulted, the frequent micturition and the thirst became a burden, and nervous irritability and restlessness appeared. At the same time the carbon dioxide carrying power of the blood dropped below the limits of the accepted normal, the hydrogen-ion concentration became definitely altered, and the rise of haemoglobin indicated definite loss of water beyond the limits usual in health. No observations were made on the circulation and the digestive system, but I have no doubt that they also shared in the general adjustment and ultimate derangement, every organ and system of the body doing its best to co-operate in reducing to a minimum the effect of this simple, though artificially produced, alteration in the conditions of life.

In the last ten years much progress has been made in extending the knowledge of the physiology of the living body. There have been valuable advances in the physiology of respiration, of the circulation, of renal secretion, of the nervous system, of general metabolism, and in the chemistry of the blood, and there has been important advance in the knowledge of how each system depends for its successful functioning on the others, and of the ways in which disturbances in one system react on the others.

THE NEED FOR INSTRUCTION IN HUMAN PHYSIOLOGY.

That there is now sufficient knowledge of human physiology to enable instruction to be given to medical students needs no further discussion, and many simple experiments suitable for practical class work in human physiology have been devised.* I believe that there can be no doubt in the minds of any that it is desirable that such instruction should be given and such practical work carried out as part of the training of medical men. In the practice of his profession the medical man must decide first of all in what manner and to what extent the functions and structures of the body and its organs are disturbed, in what particulars the adjustments for maintaining health have failed. He must then decide what external factor has caused this departure from the healthy state. If possible he must remove it, but more frequently he can only aid the body in its attempts at adjustment, and by so aiding it enable it to return to the state of co-operative functioning and efficiency that is called health. Surely, then, it is of the utmost importance that he should understand the means of adjustment that have failed, in order that he may co-operate with them in the therapeutic measures he employs.

If textbooks are any indication, the practice of medicine has so far consisted to a large extent in the recognition that certain groupings of symptoms or syndromes are indicative of certain disease processes, which must then be treated according to certain methods that have been found effective. We know, of course, that the textbooks of medicine do not reflect fairly the best practice of medicine, but they do probably indicate the prevalent methods of practice. The conclusion must be that in the practice of medicine the individual patient is not studied as carefully as he might be, and that there is too great a tendency to try to fit his signs and symptoms into one or other of the labelled syndromes or clinical pictures, and to treat accordingly. The need for the study of each individual patient was demonstrated in the war. The shock or loss of blood that resulted from a wound was frequently so great that the normal mechanisms for maintaining life were not sufficient unless help was forthcoming. The medical men did not know these normal mechanisms, nor how to help them; the physiologists did not know either; and much new work had to be done before they were able to devise effective methods of treatment. The changes consequent on gassing found most medical men and physiologists in a similar position of having to investigate along the lines of human physiology before deciding on the treatment to be adopted.

In several medical schools, to my knowledge, instruction in human physiology is given, and I have no doubt that it is so in all schools, while many are endeavouring to give it to an increasing extent. That it should enter into the training of every medical student is probably conceded, but I find that it is the almost unanimous opinion of clinical teachers that the student is not properly equipped in knowledge of physiology when he commences his clinical studies. This complaint from clinicians was readily understandable when the instruction was based on experimental work on isolated animal organs, for it is human physiology that is required at the bedside, and clinicians have always acquired some, if rather scrappy, knowledge of this from their observations on the countless experiments performed by Nature on the patients in their wards, and have learned to seek for an understanding of physiology somewhat different from that provided for the student in the preclinical years. There should have been less ground for complaint recently, and I think there has been since human physiology has been included in the courses of instruction that the student receives before entering on his clinical years.

Place in the Curriculum.

What is the best time for this instruction to be given? It would appear rational that the student should be as fully equipped as possible in the knowledge of the structure and functions of the healthy body before commencing the clinical years in which he studies patients, individuals who are inefficient because the processes of adaptation and adjustment have not been adequate. But the question is not solved so easily. It is difficult to present the methods by which health is maintained, and their limitations, without instancing the ways in which the methods may fail, and it is still more difficult for the student to grasp their importance without the appreciation of the results of their failure. A similar difficulty is seen in the teaching of anatomy, and the failure to solve this difficulty may be one of the reasons why physiology is so often laid aside by the student when he enters the wards. Human physiology must surely be taught while the student is working in the wards, and observing for himself the examples of how ill health is brought about. At present in many schools a combination of these two methods is in operation. The simpler conceptions are presented in the preclinical years, so that the student may appreciate what is meant by the physiology of the human being and have a few examples of the processes of adjustment in greater detail, and the applications of these conceptions are then observed by him

* See *Human Physiology*, by Douglas and Priestley, Oxford, 1924.

under the guidance of a clinician. Unfortunately in most instances the clinical teacher is unable to keep abreast with the advances in physiology, and is quite incapable of guiding the student along the lines that his preclinical training has opened up and prepared. This is, of course, not always the case; but it is so common that it is necessary to supplement the clinical teaching with courses of lectures in clinical applied physiology in the final years. Such lectures are useful, but are far from ideal, since they suggest that the subject cannot be dealt with at the bedside or is something other than an essential part of the practice of medicine.

By whom should the Instruction be given?

There are large gaps in our knowledge of human physiology, and the subject is so incomplete by itself that it cannot be separated from animal physiology and the physiology of organs. It is not a good educational instrument if so separated. It is therefore not advisable to alter to any great extent the courses of physiology as at present constituted, for the purpose of the preclinical years is not only to give instruction in what is to be of practical value, but also to train the mind in the meaning of biological actions and reactions, in the appreciation of accuracy, in the value of quantitation, and in the meaning of controlled observations. The courses in physiology are given at a critical period in the training of a medical man, and their educational value is of more importance in his career than any detailed facts that may be presented to him, even if perchance these can be retained in his memory for subsequent use. It is advisable, therefore, that human physiology should be taught in the preclinical years only so far as it can be fitted into a subject that must be regarded primarily as an instrument for an education in science. It is advisable, however, that every opportunity should be taken by the teacher in physiology to indicate the human or clinical applications of his science.

The head of the department of physiology in every medical school should be so eminent in his subject that it is impossible for him to have devoted much time to the careful observation of diseased persons. To recognize with clarity in any patient the points at which the intricate web of adjustments has failed is a matter of great difficulty, even for skilled clinical observers of extensive experience, so that it is obviously impossible to expect the successful physiologist to do this except in the very limited number of symptoms that have been satisfactorily investigated in human subjects. The clinician, on the other hand, can have but a hazy knowledge of the adjustments that have broken down, but he can indicate the symptoms that result from the failure and the way in which their breakdown causes inefficiency, and he can also, with the help of the pathologist, indicate the factors of interference from without that have proved too great for the individual, and perhaps also how the restoration to a healthy state may be brought about. For example, the physiologist can instruct the student in the parts played by the heart, the vasomotor system, and the respiration in the maintenance of a circulation adequate to the needs of the body; he can guide him in observations on how the rate of beating of the heart alters with exertion; and he can demonstrate Starling's law of the heart on a heart-lung preparation. On entering the wards the student meets with cases of heart failure which he recognizes by the dyspnoea, cyanosis, and oedema, and he sees that they recover with rest and perhaps digitalis and diuretics. There is no apparent connexion between his physiological training and the clinical skill of the physician whose practice he studies, and he allows physiology to slip out of thought and memory.

If the physiologist could have given point to his instruction by examples of patients who have adapted and adjusted, in spite of a damaged heart, so that economic efficiency can be maintained—some with an altered distribution of blood that gives rise to recognizable signs on physical examination of the heart, lungs, or liver, others with clearly defined capacities limited by pain on exertion—and by examples of the more advanced forms of congestive failure that follow later, the student would see the importance of the physiological adjustments and not forget them. If the physician would trace in the history of his patient the gradual breakdown of the physiological adjustments with the successive appearance of the signs and symptoms so that the student could appreciate where and how the adjustments had failed, the student would see in every patient a wonderful problem in treatment and appreciate just how far his patient can be restored to health and to what extent the symptoms and signs are indicative of permanent and progressing damage, and he would understand how the practice of medicine depends on human physiology. Instead of forgetting what he had learned, he would study it afresh that he might understand the practice of medicine. Similar examples could be cited in the practice of surgery.

At present, then, this subject, which is so important in the training of a medical man, cannot be taught satisfactorily by the physiologist alone, and probably never will be taught satisfactorily by clinicians alone, but should be presented by both, so that its full value, for both educational and utilitarian purposes, may be obtained—not by the two separately, but by the close co-operation of each.

THE NEED FOR INVESTIGATIONS.

Investigations in human physiology at the medical schools are desirable, not only for their obvious value in increasing knowledge, but also because any subject of instruction becomes dry and lifeless unless the teachers are also investigators.

The arguments for co-operation by physiologist and clinician apply even more clearly when the need for investigations in human physiology is considered. It is the clinician who sees the experiments that Nature performs; he alone can have the necessary experience to relate cause and effect and eliminate the accidental and coincident, and he alone has the skill to recognize many of the signs and symptoms of altered structure or function. But he knows little of the methods of investigation, and he has not sufficient knowledge to utilize the clues provided by the enormous amount of animal experimentation that has been performed already. The history of the development of knowledge in such subjects—to take a few obvious examples—as carbohydrate metabolism, internal secretions, cerebral localization, the control of the peripheral circulation, calcium metabolism and its relation to bone formation and to tetany, points in the same direction, since in none of these subjects could the present state of knowledge have been reached unless the physiologist had helped the clinician and the clinician the physiologist. Not only, then, for the teaching of human physiology, but also for the encouragement of investigations in human physiology, it is important to have co-operation between the physiologist and the clinician. The introduction to the report of the Medical Research Committee for 1918 contains the following:

> "It has often been pointed out that in England the work of the physiologist has been too divorced from practical medicine, and that the British school of physiology, which by the admission of other nations stands second to none elsewhere, has not been brought in this country into due contribution to the work of the physician and surgeon. No doubt this is true, and mainly perhaps because of the defects in our systems of medical education, which have allowed the physiologist to remain too much in academic retreat and the clinician too far from the laboratory and its methods."

In the ten years since that was written far too little has been done to correct the fault, but the time has not been wasted if it has resulted in the general acceptance of the truth of the contention.

CO-OPERATION BY PHYSIOLOGIST AND CLINICIAN.

How this co-operation can best be brought about must depend largely on the local conditions at each medical school. It is rare in this country to find a department of physiology that is not in a different building from the wards, and not separated from the wards by such a distance that some degree of determination is required before a member of the staff of one department will visit the other. In the newer medical schools in the United States an attempt to overcome this drawback is being made by designing school and hospital together, the department of physiology being above or below the wards, or else on the same level as the medical wards and in direct connexion

with them. Contiguity may help, but cannot solve the difficulty. The appointment of young clinicians as demonstrators in the department of physiology during the period of their graduate training must surely result in time in the clinicians of the teaching school being appreciative of the importance of human physiology in the teaching of the practice of medicine, but it cannot ensure that they will have the time to keep in touch with the advances in physiology, nor that they will be able to investigate problems in human physiology. Even if the staffs of the clinical departments include men who are free from the necessity of devoting their time primarily to practice outside the hospital, and who have facilities for investigations in laboratories in association with the wards and under the guidance of experienced clinicians, the work is not as fruitful as it might be unless the help and guidance of an experienced physiologist are available. Undoubtedly much may be done by the appointment of young clinicians to posts in the department of physiology and by the appointment to clinical posts of men trained in physiology, or by the appointment of the same men to half-time posts in each department. The successful teaching of human physiology and the successful investigation of problems in human physiology must in the long run, however, depend on co-operation by the heads of the clinical departments with the head of the department of physiology, and if this is obtained the desired attitude on the part of the junior members of their staffs is certain to follow. Such co-operation can be obtained only if the clinician is free from the necessity of earning the major part of his income outside the medical school and hospital, and if for the physiologist the burden of teaching and administration that in most schools exhausts his time and energies is made lighter.

POINTS FOR DISCUSSION.

There is little need for discussion on the meaning of human physiology, and on its importance in the training of medical students. There is much need for the exchange of views on the time in the curriculum at which it should be taught, and on the most suitable person or persons to teach it. It is most important, I believe, at this time that there should be discussion as to the practical steps to be taken so that human physiology may be efficiently taught and so that investigations in human physiology may be encouraged under conditions conducive to their successful outcome and to the increase of knowledge.

The Profession of Medicine.

INTRODUCTORY.

THE main purpose of this Educational Number of the *British Medical Journal* is to give prospective students and their parents full information about the steps that must be taken and the studies that must be pursued in order to become a registered medical practitioner. It is intended also to serve as a kind of guidebook for those wishing to know what a medical career has to offer, and for others who, having already chosen medicine as their life-work, or having entered upon it, are uncertain about the line of work for which they are best suited. As in past years, this introductory article gives an opportunity to review some aspects and tendencies of medical study and practice, in order to put the situation as we see it before those who think of devoting themselves to medicine, and thus help them to gauge their fitness for the calling and the prospects it holds out.

Intending students will find in the pages that follow an account of the course of training required of them, the places where it can be obtained, and the universities and other licensing bodies which test the knowledge gained and confer degrees or diplomas entitling successful candidates to become legally qualified medical practitioners. Sections are included also on post-graduate medical study, on the higher qualifications, both general and special, and on the many and varied spheres of professional work open to registered medical men and women at home and abroad. The details given are founded for the most part on official information, and are arranged along the customary lines.

GROUNDWORK OF MEDICAL STUDY.

The aim of a medical school should be to teach, not only the essentials of medicine, but also the right principles and methods of adding to knowledge after qualification. Such teaching, to be effective, presupposes a good general education. Next in importance is a good scientific education—a thorough grounding in the basic principles of science. Upon these the student of ordinary intelligence and industry can build up an adequate technical equipment for the practice of his profession. Medicine is an art founded on science, from which it follows that a real training is needed in science and the scientific spirit. An unfortunate tendency of the present system of teaching the preliminary subjects is to produce a temporary "cram" knowledge which is quickly forgotten after the particular examination is passed. This is not how the basic sciences should be studied. These sciences interlock with each other and with the later subjects, and, properly approached, they give a drilling in exact methods, in precise manipulations, and in vigorous reasoning which will bear immediate fruit in the clinical part of the curriculum and prove of benefit throughout professional life. A sound training in medicine seeks to raise on scientific principles a firm edifice of practical knowledge and skill. Students who hold fast to this idea will regard "cram work" as a weakness in the foundations, and therefore as a hidden danger to the superstructure. Chemistry, physics, and elementary biology prepare the way for anatomy and physiology, and so for medicine and surgery and obstetrics. Changes in the details of the curriculum are needed from time to time, but all authorities are agreed that these preliminary and intermediate sciences form the only appropriate introduction to the study of clinical medicine. The great John Hunter "studied anatomy and physiology to get help in diagnosing and treating his patients. He studied dead things to understand the living, and observed living things to understand the dead. A knowledge of how this body is made and how it works must provide the basis for all the more practical subjects of medicine."

PORTALS OF THE PROFESSION.

The obvious goal of every student is the entry of his name in the *Medical Register*, which is the official statutory list of qualified medical practitioners kept by the General Medical Council. Those who are not acquainted with the system of medical teaching and examination in these islands, and with the history of our professional institutions, may well feel bewildered at the number and variety of ways in which admission can be obtained to the *Register*. They will see in the table of contents to this Educational Number that there are no fewer than twenty-seven bodies—eighteen universities and nine corporations—which either separately or jointly issue registrable qualifications; and the number of teaching institutions is even larger. Nevertheless, although we have no single State examination in medicine—no "one portal system," as it has been termed—the medical courses of the various universities and schools in Great Britain and Ireland run on parallel lines, and the obligatory curriculum is much the same for all students. As, however, the individual teaching and examining bodies

have different standards and requirements, the choice should be made early, so that a definite plan may be followed.

If possible the decision to study for a university degree in medicine should be made by the time a boy or girl is 15. A matriculation examination or its equivalent should be attempted without delay, and the parent should ensure that the special requirements of the medical faculty of the selected university are fulfilled. As soon as this examination is disposed of work should be begun at school in the subjects of the First M.B. Few house-masters at public schools seem to be adequately informed about medical requirements under the revised curriculum, and it is doubtful if all schools are fully competent to meet the varying requirements of different authorities. It therefore behoves parents to make inquiries on their own account in order that valuable time may not be wasted during the last year or two at school. This applies to all prospective medical students, but with special force to those seeking degrees at Oxford or Cambridge and desirous of getting the best out of the university. (See note on Public Schools and Medical Students, p. 388.)

All who wish to enter the profession must comply with certain conditions. These are regulated by the General Medical Council, which is a statutory body set up under the Medical Acts; a summary of its functions and requirements is given at page 389. Many changes have lately been made in the medical and pre-medical curriculum, and this section, as well as the article on Professional Study and Examination, should be studied with care. It is the business of the General Medical Council, so far as possible, to see that a suitable kind of training and the requisite degree of knowledge are secured to the student, and it is the business of the medical schools and examining bodies to give the training and test the knowledge in accordance with the requirements of that Council. Every student, after passing examinations in the subjects of general education and in the preliminary sciences of chemistry and physics, must take a course of training at a recognized medical school, covering a period of at least five years, but usually extended to six years or more.

Examination of candidates as to their fitness to practise medicine, surgery, and obstetrics is left to the licensing bodies, which are of two kinds—the universities, and certain medical corporations in England, Scotland, and Ireland. The requirements of these licensing bodies are summarized elsewhere under separate headings. One of the functions of the General Medical Council, besides that of keeping the *Medical Register* and maintaining discipline within the profession, is to make sure that the tests at each stage do not fall below a certain standard, and that the students examined have undergone prescribed courses at approved institutions. Successful candidates eventually receive either degrees, in the case of a university, or diplomas or licences, in the case of a corporation; these qualifications entitle them to claim insertion of their names in the *Medical Register*. Every student, as soon as he obtains his qualification to practise, should at once register; otherwise he cannot hold a public medical appointment, or sign any certificate required from a legally qualified practitioner (such as a death certificate), or recover professional fees in a court of law.

Holders of diplomas and licences once made up the great majority of all medical men, especially in England and Wales. But universities have greatly multiplied during the present century, and so many practitioners are now graduates in medicine that a student at the threshold of his career will do well to consider the advantages of possessing a degree, though it may be desirable to take also a diploma or licence. The medical degrees (M.B., M.D., etc.) granted by the universities in Great Britain and Ireland are mentioned among the particulars about each university printed in later sections.

COST OF MEDICAL EDUCATION.

For the ordinary student the cost of medical education resolves itself into the cost of the training at medical school and hospital, and the cost of living during the five or six years of the curriculum. The expenses under these two main headings vary considerably. Besides differences in the charges made for instruction, there are differences in examination fees, as well as in the fees for certificates of qualification, and those who seek the higher degrees and diplomas must expect to pay more for the additional courses and tests and certificates. Again, not all students, however industrious, have the knack of imparting what they know to an examiner, and every setback due to failure in the examination room or to illness means added expenses. School and examination fees, together with the cost of board, lodging, clothes, and recreation, form the largest items of expenditure, and to these must be added the money spent on books, microscope, instruments, and so forth.

Since professional education must in any case continue for five years at least (a period exceeded by the vast majority), and since the cost of living varies much in different parts of the country, while personal expenditure varies still more, it can only be said in a general way that anyone who thinks of entering the profession should be prepared for an outlay of at least £1,500. Something between two-thirds and three-quarters of the whole amount would probably be spent on maintenance, and the rest in fees, etc., for tuition and examination. The fees charged by the different schools and licensing bodies are stated in the paragraphs relating to each on other pages of this issue. In making an estimate of the probable outlay, the many helps available nowadays for the reduction of expense should not be ignored. At nearly all the medical schools more scholarships and money prizes are offered now than in the past; at the Scottish universities bursaries are numerous; and the Carnegie Trust (whose regulations are summarized at page 400) gives pecuniary help to many Scottish students. The main thing to bear in mind is that, as compared with other professions, the period of training in medicine is long, and for most students expensive. Further guidance on this matter will be found in a memorandum,[1] drawn up by the Registrar of the General Medical Council, on the procedure to be followed in order to enter the profession. This pamphlet gives much useful information, including a comparative table of the cost of study and examination at the various institutions.

Since medical students are not commonly the sons or daughters of wealthy parents, it is usual, before setting out upon this long and exacting course of study, to weigh, not only the cost, but also the prospects. An overcrowded curriculum would be hard to face if all that could be discerned at the end of it were an overcrowded profession. Without forgetting the adage "there is always room at the top," the youth and the girl of to-day, when reckoning up their chances in any calling, will wish to know the probable numbers of their competitors for the work that is waiting to be done.

THE NUMBERS OF MEDICAL STUDENTS.

The following brief survey should be read with the notes and tables printed at page 387 on the numbers of registered students and practitioners. More new students mean more new doctors five or six years later, though, as the chart shows, there is in normal times a fairly constant wastage.

At the close of the last century the annual entry of medical students in Great Britain and Ireland had been on the average about 1,800, and then for the next thirteen

[1] *Memorandum on the Procedure to be Adopted by those who desire to enter the Profession of Medicine, with Notes on Costs and Prospects.* General Medical Council, 44, Hallam Street, Portland Place, W.1. Price 1s. post free.

years it stood at about 1,400. During the war period, although many students left to serve with the forces, the entries grew steadily larger, so that in 1918 they were 2,253, and in the following year, when demobilization was in active progress, they were 3,420. After 1919 the numbers rapidly fell, but since 1923 they have remained at a fairly steady level rather below the immediate pre-war average. In 1924 the entries were 1,043; in 1925, 1,070; in 1926, 1,260; in 1927, 1,214; and last year, 1,363.

The smaller numbers of students since 1922 are an advantage, because the excessive entries during the post-war inflation period, if it had gone on long enough, must have led to overstocking of the profession. In the past decade the numbers of new practitioners registering each year have greatly exceeded the usual pre-war figure of eleven hundred or so. The large additions to the profession in recent years brought the total number of names in the *Medical Register* up to 54,252 at the end of 1928. This is upwards of ten thousand more than the figure for 1918, almost exactly fourteen thousand more than that for 1908, and nearly twenty thousand more than that for 1898. There has been no corresponding increase of growth of population in the British Isles during the same decennial periods, and the ratio of doctors to inhabitants is therefore much higher now than ever before. It is true that the scope of medical practice has widened considerably in the meanwhile, and many fresh openings for professional work have followed advances in diagnostic, curative, and preventive methods, and the rapid development of administrative medicine. But there must be bounds to the legitimate medical needs of the community. The new regulations of the General Medical Council, though drawn up for another purpose, have tended to keep the entries of students within manageable limits, and so to maintain a balance between supply and demand.

On the whole, it may be said that, for those of good average intelligence and physique who are not afraid of work, the prospect in medicine to-day is quite favourable. The medical profession of this country is not overstocked. Its numbers are still badly distributed, though perhaps not quite so much so as at the beginning of the century.

AFTER REGISTRATION: CHOICE OF A CAREER.

The student, having passed all his tests and placed his name on the *Medical Register*, assumes the privileges and responsibilities that go with legal qualification. But after registration there is usually a period of transition between pupilage and established practice. This time may be put to the greatest advantage by serving as house-physician, house-surgeon, or casualty officer in a hospital, by working as assistant or locumtenent in private practice, or by seeing something of the world as a ship surgeon. As a preliminary to practice of whatever kind, nothing is so valuable as a year or more spent in junior hospital appointments, and all who can afford the time should look upon them as a most profitable investment.

If his mind is not made up already, the young practitioner has now to consider in which branch of the profession he can put his abilities to the best use. The choice is very wide. Among the great variety of paths open are general practice in town or country; Government service at home or abroad, including, of course, the medical branches of the Navy and Army and Air Force, and the I.M.S.; public health appointments and other administrative or official posts; institutional work, such as that of the municipal hospital, the mental hospital, and the sanatorium; and special work in scientific research and teaching, or in one of the many subdivisions of clinical medicine and surgery. Most of these careers are discussed in some detail in the later sections of this Educational Number, but a few words may be said here about general practice and the work of a consultant or specialist.

Further information and advice on such matters will be found in the *Handbook for Recently Qualified Medical Practitioners*, published by the British Medical Association.[1] This comprises articles on openings for members of the profession; on practical aspects of medical work; on registration and the privileges of practitioners; on practice under the Insurance Acts; on post-graduation study and special diplomas; and on societies undertaking individual medical defence. The section dealing with practical aspects of medical work embodies much sound advice on professional conduct in general, on common medico-legal difficulties, and on the relations between doctor and patient and one doctor and another.

GENERAL PRACTICE.

General medical practice has hitherto been, and still is, the destination of the great bulk of students. It is estimated that three-quarters at least of those who pass out of the medical schools become "family doctors" sooner or later. The work is onerous and the pay too often inadequate; but it is a full life rich in human interest, and many of the very best students, now as formerly, choose general practice as a career.

This field of professional life is usually entered in one of three ways. The newcomer may take a house, put up a plate, and wait for work to come to him; he may buy the goodwill of a practice rendered vacant by retirement or death; or he may become a partner in an established firm. The first is more risky than the second, and the second than the third. A well-managed partnership of three or more has this advantage over single-handed practice, that it allows each partner leisure for recreation and for keeping up with the progress of medicine. Success in private practice demands a great deal of knowledge beyond that gained at the medical schools, and hence a man is more likely to be accepted as a partner, or to do well on his own account, if he has already some experience as an assistant or deputy. A good many general practitioners, therefore, begin their work as assistants, and of these few find cause to regret the time spent in learning the ropes under the eye of an experienced senior. As the circumstances of general practice vary much from place to place, it is usually best to serve this "post-graduate apprenticeship" under conditions resembling those to be met later.

The general practitioner is sometimes slightingly referred to as one who has been driven by circumstances into a position which demands so much knowledge of many things that it is almost impossible for him to be up to date and thoroughly well informed on any one subject. It is beyond human power for the man in general practice to be a specialist in every department of medicine, but his outlook on disease is, in many respects, more comprehensive than that of the man whose whole life is devoted to perfecting himself in the technique and minutiae of one subject to which he gives all his energy and time. Both types of workers are necessary in these days, but it is becoming more and more fashionable for well-to-do patients to seek the opinion of so-called specialists, no matter what the ailment may be. To balance this extravagance of specialism, it is well that the public should be reminded that human organs are not parcelled out into so many pigeon-holes to be dealt with separately, but that they each form an integral part of a great and complex mechanism, any part of which going wrong inevitably throws the whole machinery out of gear. The good general practitioner possesses powers of perspective in disease that are denied to the specialist, and he must in the nature of things remain not only the most useful and encyclopaedic working unit of our profession, but also the member of it to whom, at least in the first instance, the public, in their

[1] *Handbook for Recently Qualified Medical Practitioners.* British Medical Association, Tavistock Square, W.C.1. (3s. 6d. net; post free 3s. 9d.)

own interest, should apply for relief to their ailments. The opportunities he has of seeing his patients repeatedly for minor disorders as well as for serious illnesses; the knowledge he acquires of their idiosyncrasies, their family history, habits of life, and social circumstances; his experience of the disease tendencies to which they have been born; and a hundred other details which are learnt only after long and confidential intercourse with his clients, make the general practitioner, of all medical men, the most important. His daily task is to lay the foundations of diagnosis, prognosis, and treatment. It has been said with truth that general practice is the most fruitful field for the study of the natural history of disease in the living body.

The value of the work done by the family medical attendant is better appreciated now than in the past, and it is more fully recognized that an efficient medical service must be based upon the skill and devotion of a body of general practitioners familiar with the aims and methods of preventive medicine. The doctor of to-day takes a wide view of his duty towards the environment and the habits of his clientele; unlike the doctor of yesterday, his time is not wholly spent in treating developed disease in individuals. As knowledge accumulates he will come more and more to study early disturbances of function and the maintenance of bodily and mental health in varying conditions of life and work. While this is all to the good, it cannot be denied that encroachments on private medical practice are perpetually being made under the auspices of the State or of the municipality or of voluntary bodies. If such inroads threatened only the material interests of the individual doctor they might have to be endured, but in the long run many of them must react against the public interest also. Another trial arises from the multiplication of official requirements and administrative checks imposed by public authorities. Apart from the clerical drudgery thus put upon him, these new demands tend to cramp the doctor's independence of judgement and action and to divert his mind from purely medical duties.

The national system of compulsory health insurance, now more than seventeen years old, has had a profound influence on general medical practice in this country, so much so that it is already difficult to call up a clear picture of what the conditions were like in working-class practices less than a generation ago. The Insurance Acts provide domiciliary medical attendance for nearly fifteen million persons, and more than 17,000 members of our profession undertake responsibility for the medical care of this vast section of the community. Thus the bulk of the general practitioners of the country now give, in large or small measure, medical attendance and treatment under a system embracing almost the whole working population. These practitioners, by placing their names on the panel (or medical list) signify their assent to the terms of service set out in the Medical Benefit Regulations and other relevant provisions. It would have been strange indeed if a measure so far-reaching and so complex had not brought about great changes in general practice, with some detriment to the freedom of the individual doctor. On the other hand, the panel system admittedly gives a better service than was provided under the old "club" arrangements, though it is by no means as complete or as effective as it might be made. Some of its worst faults have been removed through the efforts of the Insurance Acts Committee of the British Medical Association, which represents the interests of the insurance practitioners in all negotiations with the Ministry of Health. As yet, the national health insurance scheme does not include the dependants of wage-earners. What will happen if its scope is widened in this and other directions? Among students of present tendencies and probable future developments there are some who see in all these the oncoming of a complete State-controlled medical service.

CONSULTANT AND SPECIALIST PRACTICE.

The term "consulting practice" may be said to comprise in ordinary usage the work of the general physician (or "internist," as he is called abroad), that of the general surgical consultant or operating surgeon, and that of the gynaecologist and obstetrician. These are the three large divisions of consulting practice, as distinct from general practice, which, though they imply some restriction, yet call for a wide range of activity and outlook, in contrast with the smaller ambit of a "specialty" in the narrow sense. Of these main divisions the third is obviously the most limited, but on several grounds it can claim to rank as something larger and more comprehensive than the other specialties. It is impossible, however, to draw a sharp line between consulting practice and specialist practice. Most general consultants, whether medical or surgical, are specialists in some branch of their practice, and most specialists are consultants in the sense that their work largely comes to them through the recommendation of general practitioners, with whom they act (or should act) in a consultative capacity. In any case, whoever holds himself out as one or the other, or both, must be assumed to have knowledge and skill above the ordinary.

Whether his specialty be large or small, the specialist should possess, as a background to his expert attainments, a broad knowledge of medicine and surgery. Intensive study is required of him, and he should look on hospital posts, especially teaching posts, as a vital part of his higher education. For him, as for practitioners of all branches, success will depend in the long run, not only on mental gifts, special experience, and capacity for hard work, but on the possession of those qualities which inspire confidence both in patients and in colleagues. Moreover, since he can scarcely hope at first to pay his way by consulting work or by the exercise of a specialty, he must either have private sources of income or be prepared, by teaching or in other ways, to make ends meet. If while in preparation for his life-work he can undertake some piece of research bearing upon his clinical studies, this is most advisable, and every opportunity should be seized of paying visits to foreign clinics. Competition in this branch of practice is very keen, as anyone can prove by counting the name-plates on the doors in the Harley Street area of London, or in corresponding parts of other large cities. Expenses are heavy, and the young consultant or specialist may have to go through a long time of training and waiting before he makes an income; but on the other hand success, when it comes, is liberally rewarded.

A comparatively new feature of medical life, especially in the larger industrial towns of the North of England, is the growing number of "general practitioner specialists," who combine ordinary panel practice with much surgical or other special work in well-equipped local hospitals which admit patients in different categories according to their means. Though the fees are small compared with those earned by operating surgeons and specialists in London, the work is by no means unremunerative, and it adds a great deal to the interest of the daily round.

Additional degrees and diplomas are important factors in securing election to the visiting staff of a large hospital, and a few remarks about them may be made here. Beyond the qualifications, such as Bachelor or Licentiate, which admit to the *Medical Register*, most of the licensing bodies bestow higher titles, such as Doctor, Master, or Fellow, after further tests. A considerable number of those who have graduated M.B. at a university, including many general practitioners, proceed later to the doctorate, and an M.D. degree is certainly advantageous to anyone in consulting medical practice. When applying for the post of physician to a hospital it is always useful, and may be obligatory, to hold also the Membership of one of the three

Royal Colleges of Physicians, according to the part of the British Isles in which the hospital is situated. So, too, the Fellowship of one of the three Royal Colleges of Surgeons should be obtained by those seeking surgical appointments, and the degree of Master of Surgery is an added distinction. There are also diplomas in a growing number of special branches of work—such as public health, tropical medicine, ophthalmology, laryngology, radiology, tuberculosis, psychological medicine, and midwifery—which are superfluous for most practitioners, but may be useful or even indispensable for those who intend to devote themselves to one or other of these subjects. Information about the special diplomas open to qualified practitioners, and about higher degrees, will be found in other parts of this issue.

FINANCIAL AND SOCIAL ASPECTS.

"It is a reasonable and proper question for anyone entering on a medical career to ask, What return may I expect from my work? Not less reasonable and proper is it that such an inquiry should include an examination of the financial prospect. The struggle for existence is imposed on most of us, and even a larger success of this order implies no unworthy ambition. Medicine professes no prospect of a ready and great fortune, but to diligence and thoroughness it guarantees at least a modest competence; if the making of money is the principal aim, the searcher had better turn elsewhere."[1]

The pecuniary disadvantages of medicine are the long and costly training, the time of waiting after qualification before the practitioner can count upon an adequate income, and the heavy working expenses in proportion to gross earnings. On the other hand, it affords a fairly certain means of livelihood, with unrivalled opportunities for exercise of the intellect in the service of others. The counterpart of the briefless barrister is practically unknown in our profession. But while no doctor who is willing and able to work need starve, it should be clearly grasped by all who think of adopting it as a career that medicine is a path to fortune only for the few. The distinguishing feature of a liberal profession in contrast with a trade is that it is followed more for the general good than for individual profit. Whatever the branch of work chosen, it is rare for a doctor to become what a business man would consider even moderately rich by the practice of his profession. Yet, if medicine, from the financial point of view, offers to most men little more than the means of livelihood, in its social and cultural aspects the outlook is far brighter. The practitioner's lot is unlike that of many whose business gives little scope to the higher faculties of the mind, for he lives in, and by, the exercise of his intellectual powers. Moreover, the culture which in past centuries belonged to the physician alone has spread into all ranks of the profession. The steady improvement in the education, general as well as technical, of the practitioner has added much to his influence with the public, and has been a large factor in raising his social status during the seventy years that have passed since the General Medical Council was constituted under the first Medical Act. The doctor of to-day holds an excellent position among his neighbours, and is the friend and confidant of many of his patients. Many men go further, and take a leading part in the public life of their district. There are conspicuous instances of the good work in this direction that has been accomplished during an arduous professional career. A proof of the all-round value of a medical training is the way in which it fits men for leadership.

PROFESSIONAL ORGANIZATION.

It is a sound rule of conduct that the new practitioner should associate himself as cordially as possible with his colleagues. The spirit of comradeship, which adds so much to the value and happiness of undergraduate study, should be preserved, both for its own sake and because no doctor, whatever the nature of his work, can safely stand aside from his fellows. Individuals and isolated groups of practitioners are always handicapped when they try to defend their interests against organized bodies, whether these are Government departments, local authorities, or bodies of workmen. In the ordinary way of practice the individual doctor is well able to deal with the individual patient and the patient's friends, but he cannot engage successfully in single combat with outside organizations. But apart from such motives of self-interest, every one of us owes a duty to our profession, and the doctor who holds aloof fails in that duty. Medical men and women must therefore band themselves together, and the first step after graduation should be to become an active member of the British Medical Association. Besides having behind him the machinery and the influence of a world-wide professional body, a young practitioner will find in the meetings of his local Division, and in the Annual Meetings of the Association, many opportunities for keeping abreast of new work in medicine and for friendly intercourse with colleagues. Another thing that no new graduate should fail to do is to join one of the professional societies which for a small yearly sum undertake individual legal defence of their members. It is folly to put this off, even for a day. The need for protection may arise out of the first case attended in hospital or in private practice.

The British Medical Association was founded in 1832 to promote the medical sciences and to maintain the honour and interests of the profession; a brief note on its constitution and activities will be found at page 442. The Association, with Branches throughout the British Empire and a membership of nearly 35,000, is the only body that can act for the profession as a whole and speak in its name. The record of ninety-seven years' work shows that vocational organization, wisely directed, can combine service for its members with service for the public; but much still remains to be done in both ways. Every medical man and woman should try to take a share in some at least of the various movements, scientific or social or political, with which the Association has identified itself.

PROFESSIONAL STUDY AND EXAMINATION.

THE MEDICAL CURRICULUM TO-DAY.

IN 1922 the General Medical Council prescribed a readjustment of the medical curriculum, to come into force at the beginning of the following year. The scheme adopted was in effect a compromise between several "schools of thought" which had been debating the matter for fifteen years or more. In this readjustment, among other things, increased emphasis was placed upon sufficient opportunity being afforded for the study, both theoretical and clinical, of those subjects which are now so essential in connexion with the treatment centres of a local authority, such as ophthalmology, venereal diseases, orthopaedics, ante-natal conditions, and infant welfare. Our article printed at page 389 on the functions and requirements of the General Medical Council includes the text of the resolutions and recommendations of the Council which have applied since the beginning of 1923. We summarize below the leading features of the revised scheme of professional study and examination, and indicate the importance attached by the Council to the preventive aspects of medicine. The first qualifying examinations based upon this readjusted curriculum were held last year.

The minimum age for registration as a medical student is now 17 years. There has been no formal lengthening of the medical curriculum under the revised scheme, but in practice it has been added to by transferring to preliminary study and examination the subjects of elementary physics and chemistry in their purely scientific aspects.

Thus, in addition to passing a preliminary examination in general education, an examination (written, oral, and practical) in the elements of physics and chemistry is required by the General Medical Council before the admission of a name to the Students' Register. In the applications of these two subjects to the professional courses —as in biophysics, biochemistry, and pharmacological chemistry—appropriate instruction is to continue throughout the curriculum, and is to be tested by examination, so that the student shall no longer be able to put behind him as past and done with the knowledge which he acquired as a preliminary. If he has had no facilities at school or otherwise for obtaining what is necessary for the preliminary or pre-registration examination in chemistry and physics, then he can come for it to the university or medical school, but study for this will not count as part of the medical curriculum. In elementary biology comparatively few secondary schools are equipped for tuition, but the General Medical Council has suggested an arrangement for utilizing the work of such schools as are qualified for the purpose. The examination in elementary biology will not be "pre-curriculum," but the instruction may be so, and a licensing body can allow students who so desire to sit for the examination immediately after matriculation. Here again, however, it is the wish of the Council that the applications of biology to medicine, surgery, and midwifery shall continue to receive adequate attention throughout the courses.

A Block System of Study.

Besides the resolutions of the General Medical Council in regard to professional education and examination printed elsewhere at page 391 a series of additional resolutions was adopted in 1922, as follows:

(*a*) That throughout the whole period of study the attention of the student should be directed by his teachers to the importance of the preventive aspects of medicine;

(*b*) That each licensing body should make adequate arrangements for the effective correlation of the several subjects of study throughout its curriculum;

(*c*) That the teaching of anatomy and physiology should include as a regular part of the courses the demonstration on the living human body of structure and function;

(*d*) That the curriculum should be so arranged that a minimum period of three years shall in every case be available for study after the completion by the student of the Professional Examinations in anatomy and physiology held at the close of the second year;

(*e*) That the curriculum should be so framed as to afford sufficient opportunities for the study, during the last three years of the course, of physics, chemistry, biology, anatomy, and physiology in their practical application to Medicine, Surgery, and Midwifery, and that the student's knowledge of these applications should be subject to test in the Final Examination;

(*f*) That before the student is admitted to his clinical appointments he should have received practical instruction in clinical methods and in the recognition and interpretation of physical signs;

(*g*) That instruction should be given, in the courses of Forensic Medicine and Public Health or otherwise, on the duties which devolve upon practitioners in their relation to the State, and on the generally recognized rules of medical ethics. Attention should be called to all *Notices* on these subjects issued by the General Medical Council.

The Council, it will be noted, attaches great importance to the reservation of sufficient time for the later subjects of study, free from all worries about passing the examinations of the earlier parts. To that end it recommends what is practically a block system. A minimum of three years should be available, not merely after the courses of anatomy and physiology have been taken, but after the examinations in these subjects have been passed.

Examination Reform.

Another notable feature is that in assessing marks in the several examinations account may be taken of "duly attested records of the work done by the candidate throughout his course of study" in the subject. This is an effort to meet the long felt difficulty that a man's mental agility, or the want of it, counts far too much in the examination room. The difficulty is real, but the remedy is not easy, and the Council has been wise in the cautious approach it makes towards a solution. Where, as in the examinations for the various conjoint diplomas, a student will only by chance come before his own teacher as an examiner, absolute impartiality in the attested records will be necessary. On the other hand, at the universities, where the teacher is almost always one of the examiners, no personal like or dislike of a student must influence the report of the internal to the external examiner. The class records should, of course, be available, but the scheme will put a serious ethical obligation on all concerned, and the Council will doubtless watch its operation with keen and critical interest.

Training in Preventive Medicine.

The first of the resolutions quoted above should be borne in mind by every teacher throughout the whole curriculum, and not merely in the clinical subjects. All the earlier subjects—physics, chemistry, biology, physiology, anatomy, and, of course, pathology, bacteriology, and therapeutics also—afford opportunities from the very beginning for instilling into the mind of the student the necessity for his keeping constantly in view, in all the advice and treatment he may give throughout his professional life, the primary importance of promoting the general health of those who entrust themselves to his care, and of preventing trivial ailments from developing into definite disease.

NUMBERS OF THE MEDICAL PROFESSION.

A Review of Fifty Years.

In order to present a general view of the numerical strength of the medical profession during the past half-century we have extracted from the records and set down below in parallel columns the total number of names in the *Medical Register* on December 31st of each year, and the numbers added annually by registration between 1879 and 1928.

Numerical State of the "Medical Register."

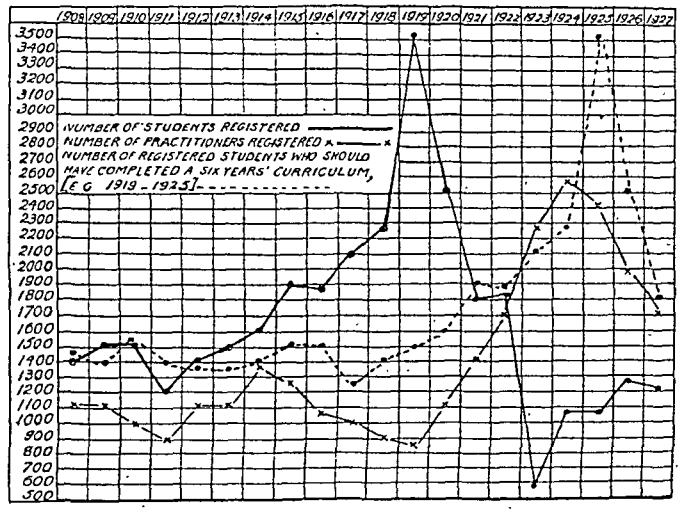
Year	Names added in Year	Total No. on Dec. 31	Year.	Names added in Year.	Total No on Dec. 31
1879 ...	996 ...	22,516	1904 ...	1,168 ...	38,492
1880 ...	1,123 ...	22,936	1905 ...	1,240 ...	39,060
1881 ...	1,063 ...	23,275	1906 ...	1,197 ...	39,529
1882 ...	1,171 ...	23,801	1907 ...	1,221 ...	39,827
1883 ...	1,304 ...	24,517	1908 ...	1,137 ...	40,257
1884 ...	1,388 ...	25,321	1909 ...	1,143 ...	39,818
1885 ...	1,377 ...	25,993	1910 ...	1,062 ...	40,483
1886 ...	1,431 ...	26,452	1911 ...	1,042 ...	40,913
1887 ...	1,531 ...	27,246	1912 ...	1,157 ...	41,439
1888 ...	1,184 ...	27,939	1913 ...	1,168 ...	41,910
1889 ..	1,305 ..	28,318	1914 ...	1,433 ...	42,378
1890 ..	1,266 ...	29,163	1915 ...	1,526 ...	43,225
1891 ..	1,345 ...	29,555	1916 ...	1,202 ...	43,481
1892 ...	1,513 ...	30,590	1917 ...	1,134 ..	43,819
1893 ...	1,579 .	31,644	1918 ...	1,077 ...	43,926
1894 ...	1,426 ...	32,637	1919 ..	1,322 ...	44,510
1895 .	1,446 ...	33,601	1920 ...	1,457 ..	44,761
1896 ...	1,385 ...	34,478	1921 ...	1,760 ...	45,409
1897 ...	1,230 ...	34,642	1922 ...	1,983 ...	46,476
1898 ...	1,210 ...	35,057	1923 ..	2,482 ...	48,140
1899 ...	1,351 ..	35,836	1924 ...	2,796 ...	50,035
1900 ...	1,345 ...	36,355	1925 ...	2,570 ..	51,738
1901 ...	1,318 .	36,912	1926 ...	2,120 ...	52,614
1902 ...	1,275 .	37,232	1927 ..	1,941 ...	53,769
1903 ..	1,233 .	37,878	1928 ..	1,656 ...	54,252

The varying proportion of registered medical practitioners to population during the period under review is shown in the following table. This sets out the total population of the British Isles at each decennial census since 1881, and the number of names on the *Register* in the same year; also the corresponding totals for the mid-census year 1926.

Proportion of Practitioners to Population.

Year.	Registered Practitioners.	Population, British Isles.
1881	23,275	35,241,482
1891	29,555	38,104,975
1901	33,912	41,976,827
1911	40,913	45,370,530
1921	45,408	47,146,506
1926	52,514	48,190,000

These figures show a steady increase in the ratio of doctors to population, which was accelerated during the years immediately following the war. The number of registered practitioners at the end of 1921 was nearly double the number at the end of 1881, but the population of Great Britain and Ireland within that period of forty years only increased by about 34 per cent. There is now considerably more than one name in the *Medical Register* to every thousand of population. In the United States of America it is estimated that there is one medical practitioner to every 753 people. Next to the United States the British Isles appear to have the highest proportion of practitioners to population. Austria has approximately one doctor to every 900 inhabitants; Switzerland 1 to 1,135; Denmark 1 to 1,200; Germany 1 to 1,320; Hungary 1 to 1,480; and Czechoslovakia 1 to 1,970.



Numbers of medical students and practitioners, 1908 to 1927.

REGISTRATION OF STUDENTS AND PRACTITIONERS.

The relation between the numbers of new students and those of newly qualified practitioners during recent years is shown in the accompanying chart, reproduced from the report of the Finance Committee of the General Medical Council for 1928.

The figures for the registration of practitioners year by year apply only to those whose names were entered on the British list, entries in the colonial and foreign lists of the *Medical Register* being excluded; hence the slight discrepancy between the totals indicated in this chart and those given in our tables printed above. The chart brings out in a striking way the difference between the number of registered students who should have completed a six years' curriculum in a given year and the number of newly qualified practitioners who in fact registered in that year. In 1919, following the armistice, there was an enormous entry of students; but a considerable proportion dropped out of the running year by year, and in 1925 the number of those who qualified fell short of expectations by nearly 1,000. Since then the two figures have approached each other again, and it is reasonable to suppose that the pre-war relationship between them will be resumed. Some further remarks on the numbers of medical students in recent years will be found in our introductory article on the profession of medicine.

PUBLIC SCHOOLS AND MEDICAL STUDENTS.

[FROM A CORRESPONDENT.]

ANYONE who has to meet large numbers of parents of public school boys who are destined to take up medicine must hear frequent complaints about a boy being "let down by his public school." A boy is suddenly removed from school and rushed to a crammer to be prepared for some subject necessary for a particular preliminary examination which has been inadvertently omitted from his school curriculum. This is usually due to the ignorance of the parent, and often, it must be admitted, of a medical parent.

The fact is that the demands of different schools and universities are not identical. Some university teachers find that their students come with inadequate preparation in the ancillary sciences, and are of opinion that a year's teaching by university methods can do as much as two years at school. Others think that on general grounds it is better to get the students a little later and to avoid the trouble of arranging pre-registration courses at a university. This difference of opinion is reflected in the lack of uniformity of demands on the candidate for registration. In a few years the present experiments will presumably have brought some conclusive results. Either the standard of "pre-registration" teaching in secondary schools and public schools will be improved, or the universities will have taken up the work at an earlier stage. At the present time, however, it is imperative that parents should realize the difficulties and themselves take on the responsibility of making a serious decision which may save a year's time and expense. The following steps seem to be essential.

If possible the decision to study for a university degree in medicine should be made by the time a boy or girl is 15. The parent, having decided upon the university, should discover what are the essential subjects for matriculation in the *medical* faculty of that particular university and arrange with the housemaster that these subjects shall be taken in the School Leaving Certificate Examination or its equivalent. When this examination has been passed with the necessary "credits," as it should be, at the age of 16, the parent should then discover what pre-registration examinations are required by the faculty of the university, and, after consultation with the housemaster and other inquiries, decide whether the school in question can teach these subjects efficiently, so as to ensure a reasonable chance of a boy passing the necessary examination in due time.

It can be assumed that the public schools wish to retain their scholars till they pass the pre-registration examinations, and that they are at the present time doing all they can to fit themselves for the new duties. It cannot, however, be assumed that each school can prepare students for the particular demands of each medical faculty; still less can it be assumed that each housemaster is fully aware of the different subjects and standards required by the many different authorities. On the other hand, it cannot be too strongly emphasized that any parent of a prospective medical student must make careful inquiries and take an intelligent interest in the school curriculum for two or three years before his son or daughter is to enter a university. The non-medical parent may perhaps require to be informed that the General Medical Council's demands before registration are not identical with those of the universities before matriculation.

THE GENERAL MEDICAL COUNCIL.

THE General Medical Council was established by the Medical Act, 1858, in order "that persons requiring medical aid should be enabled to distinguish qualified from unqualified practitioners." It consists of eighteen members appointed by the Universities in the United Kingdom having medical faculties; of nine members appointed by the Medical Corporations, such as the Royal Colleges of Physicians and Surgeons; of five members appointed by His Majesty in Council; and of six members directly elected by members of the profession as a whole—a total of thirty-eight. To these are added three dentists who are members of the Dental Board, and are appointed for dental business. Although the eighteen members appointed by the Universities and the five members appointed by His Majesty in Council may all be laymen, only one layman has so far been appointed and that was by the Privy Council in 1926.

The Council's offices are at 44, Hallam Street, Portland Place, London, W.1, and it has Branch Offices at 12, Queen Street, Edinburgh, and 35, Dawson Street, Dublin.

The Council exists for the protection of the public and not of the profession. Its principal functions are three. First, to keep the *Medical Register*; second, to see that the name of no person is entered thereon as qualified unless he has had an adequate professional education, and to remove therefrom the names of qualified persons who are no longer entitled to public confidence; and third, to provide for the publication of the *British Pharmacopœia*. It is the appearance of a name upon the *Medical Register*, and not the possession of a degree or diploma, that constitutes a person a duly or legally qualified practitioner of medicine.

The Council has no power to make rules in regard to the medical curriculum or examination, but it can pass resolutions and make recommendations relating thereto, and, if any of these were ignored by the licensing bodies, it would be open to the Council to make representations to the Privy Council, which, if it thought fit, might order that the qualifications obtained from such bodies should not be registrable.

The name of any medical practitioner who has been convicted of felony or misdemeanour, or who is proved before the Council itself to have been guilty of "infamous conduct in a professional respect," may be erased from the *Medical Register*.

The Medical Acts prohibit attempts being made to impose restriction as to any theory of medicine or surgery, and, once a practitioner has been trained and tested in the knowledge essential for public safety, he may adopt any "theory" of medicine or surgery in which he honestly believes. The Medical Acts do not prohibit the practice of medicine by unregistered persons, but if they "wilfully and falsely" assume any title implying registration they are liable to prosecution. In this respect the Medical Acts differ from the Midwives and the Dentists Acts, which entirely preclude the practice of midwifery or dentistry by unregistered persons. Unregistered medical practitioners, however, are under certain disabilities, for they cannot recover charges for medical or surgical attendance, etc., in a court of law; they cannot hold an appointment as a medical officer in the Military or Naval Services, or on ships; they cannot give any valid certificate which is required by any Act from a medical practitioner—for example, certificate of death; and they cannot obtain dangerous drugs or attend cases of venereal disease.

An account of the recommendations that the Council has drawn up in respect of the education of medical students here follows.

REGISTRATION OF MEDICAL STUDENTS.

The Council recommends that every intending student of medicine should be registered as such at one of its three offices, whose addresses are given on page 390.

Candidates must produce evidence (*a*) that they have attained the age of 17 years; (*b*) that they have passed an examination in general education which is accepted for matriculation or entrance to the Faculties of Arts or Pure Science in a university in the United Kingdom; and in addition thereto that they have passed an examination in elementary chemistry and elementary physics conducted or recognized by one of the licensing bodies.

Application for registration should be addressed to the Registrar for the division of the United Kingdom in which the applicant is residing—England and Wales, or Scotland, or Ireland. It must be made on a special form, which can be obtained from one of the offices of the General Medical Council itself or from one of the various licensing bodies and medical schools.

The regulations with regard to registration apply equally to medical and dental students, with the exception that, in the case of the latter, pupilage with a registered dental practitioner may be regarded as a commencement of professional study, and that applications for registration should be addressed to the London office only.

PROFESSIONAL EDUCATION.

The rule is that it is only from the date which appears against his name in the *Students Register* that the medical student's career officially begins; thereafter five years at least must pass before he can present himself for the final examination for any diploma which entitles its lawful possessor to registration as a qualified medical practitioner under the Medical Acts; but to meet the circumstances brought about by the dates at which sessions of the medical schools begin and end, the close of the fifth year may be reckoned as occurring at the expiration of fifty-seven months from the date of registration. In any case, the period of five years must be one of bona-fide study; and in every course the following subjects should be included:

(i) Elements of General Biology, including an introduction to Embryology. This course, if the licensing bodies permit, may be taken before registration, and the examination may be passed immediately after registration.
(ii) Chemistry, Physics, and Biology in their application to Medicine.
(iii) Human Anatomy and Physiology, including Histology, Elements of Embryology, Biochemistry, and Biophysics.
(iv) Elementary Bacteriology, prior to regular clinical appointments.
(v) Pathology, general, special, and clinical, and Morbid Anatomy.
(vi) Pharmacology and Materia Medica, to be taken concurrently with clinical instruction.
(vii) Forensic Medicine, Hygiene, and Public Health.
(viii) Medicine, including Applied Anatomy and Physiology, Clinical Pathology and Therapeutics, Children's Diseases, Acute Infectious Diseases, Tuberculosis, Mental Diseases, Skin Diseases, and Vaccination.
(ix) Surgery, including Applied Anatomy and Physiology and Clinical Pathology, Anæsthetics, Diseases of the Eye, Ear, Throat, and Nose, Radiology, Venereal Diseases, and Orthopædics.
(x) Midwifery and Diseases of Women, including ante-natal conditions and infant hygiene.

The Council recommends that during the last three of the five academic years clinical subjects shall be studied.

The first two years must be passed at a university, or at a school of medicine recognized by any of the licensing bodies enumerated in the schedule to the Medical Act of 1858, and the remainder must be devoted to clinical work at any public hospital or dispensary at home or abroad which is recognized by a licensing body.

SPECIAL CONSIDERATIONS.

The requirements of the General Medical Council in respect of the education of those who desire to enter the medical profession have now been given in outline, but before leaving this part of the subject the steps which the aspirant should take may be rehearsed in their due order:

(1) Pass an examination in arts;
(2) Pass an examination conducted or recognized by a licensing body in elementary physics and elementary chemistry;
(3) Having attained the age of 17, enter himself at a university or at a medical school recognized by one of the licensing bodies;
(4) Obtain registration as a medical student;
(5) Study for a minimum of five years certain prescribed subjects;
(6) Meanwhile pass sundry intermediate examinations; and at the end of the fifth year pass a "qualifying examination" which will entitle him to receive from a licensing body a legal authority to practise.

The Minimum Period.—It must be remembered that the period of five years is a minimum; more is often required even by the man of good abilities and reasonable industry,

and some of the universities prescribe a longer period. Besides these qualities a student, to obtain a registrable qualification in the minimum period of five years, or fifty-seven months, must have a considerable amount of good luck; in other words, he must keep in good health through every term, and never fail at a single examination. Thus, for instance, before presenting himself for any examination he must be "signed up" for the subjects covered by that examination; this means that his teachers have to certify that he has diligently attended the required number of lectures or classes in the subjects in question. If, however, the student happens to be ill during the term when such lectures or classes are taking place he may miss enough of them to make it impossible for him to be signed up. Then, again, should he fail to satisfy the examiners at some examination, he cannot present himself for re-examination for at least three months. This generally entails further consequences, because, apart from the student's success at the next stage in his career being imperilled by the need for restudying the subjects in which he has failed, the Examining Boards usually insist upon a definite interval elapsing between one examination and the next. Further, many Boards have refused to recognize lectures and classes which have been attended before the student has passed the requisite examination in earlier subjects, and the Council now recommends that the professional examinations in anatomy and physiology be passed before the minimum period of three years' subsequent study be entered on; in other words, no clinical study should count as such until these examinations have been successfully completed. Failure at an examination may thus not only mean deferment of the date of examinations, but deferment of the beginning of the student's study of certain subjects. It is thus exceedingly easy for a student to fail to qualify in five years, and, as a fact, the majority of students take longer.

In speaking of the minimum period, it is to be remembered also that that time is only sufficient to gain a registrable qualification, such as a Bachelorship of Medicine or Surgery or the diplomas of the Royal Colleges. Those who wish to take a higher qualification—for instance, the F.R.C.S.Eng.—must prolong their work for another year or more. So, too, must in some cases those who desire to convert their Bachelorship into a Doctorate. This may entail further formal examination, but at some universities the M.D. is obtainable on presentation of a thesis when the Bachelor has attained a certain age and has practised for a certain number of years. However, a student's career proper may be considered, perhaps, to have ended when he obtains his first registrable qualification, for while preparing himself for any further tests he can, and usually does, hold some junior appointment which more or less covers his expenses.

MEMORANDUM ON STUDENTS' REGISTRATION.

The following memorandum has been drawn up by the Registrar of the General Medical Council as to the procedure for those who desire to be registered as medical or dental students.

The requirements for the registration of medical and dental students are the same, and every intending student should, in his own interest, register as soon as he commences his professional curriculum.

A recognized examination in general education must first be passed. If the student intends to obtain a university degree, he should apply to the university he selects for information as to its matriculation requirements in arts or pure science, or as to any examinations which may be accepted in fulfilment thereof. If the student intends to obtain a qualification from one of the licensing corporations (these are the Conjoint Boards in England, Scotland, and Ireland, the Society of Apothecaries of London, and the Apothecaries' Hall of Dublin), any of the examinations indicated below will be accepted. The subjects required are: (1) English, (2) Mathematics (elementary), (3) a language other than English, and (4) a fourth subject as required by the regulations of the particular examination, to be chosen from the following—namely, History, Geography, Physical Science, Natural Science, Latin, Greek, Hebrew, French, German, or other language accepted by a university for matriculation.

The requirements of the preliminary examination in general education being satisfied, it is then necessary for the student to pass a further or pre-registration examination (theoretical and practical) in elementary chemistry and elementary physics, which is conducted or recognized by one of the licensing bodies—that is, a university or licensing corporation. These subjects must be passed *in addition* to those included in the preliminary examination—for example, chemistry taken as one of the four required subjects in the preliminary examination cannot also count as one of the subjects of the pre-registration examination. These subjects may be studied at a university or medical school, or at a secondary school or other institution recognized by the body whose pre-registration examination it is intended to take. The student should, in every case, write beforehand to the body whose qualification he desires to obtain (a list will be found below) for information in regard to its requirements for this examination.

These two examinations (in general education and in physics and chemistry) having been passed and the student having attained the age of 17 years, he should apply to one of the universities or one of the medical schools for admission to its course of medical study. When medical study has been begun, he should apply to the Dean of the school, or to the Registrar of one of the branches of the General Medical Council, for a form of application for registration as a student, and should have it completed and sent in to one of the Branch Councils as soon as possible. There is no fee for this registration. The medical curriculum will extend for at least five years, and the dental curriculum for at least four years, from the date of registration as a student.

A student who has, before registration, studied the subject of elementary biology at an institution recognized by one of the licensing bodies may, if the body sees fit, be admitted to the professional examination in this subject immediately after his registration as a student. For information in regard to this he should apply to the body whose medical qualification he seeks.

A dental student may commence his curriculum, if he so desires, as a pupil in dental mechanics of a registered dental practitioner; but study at a dental school is to be preferred. If, however, he is apprenticed to a dental practitioner, he will have to devote twice as much time to instruction in dental mechanics as he would if he had taken this subject in a school. This will have the effect of lengthening the curriculum. In any case a student can only obtain a concession of twelve months out of the four years' curriculum.

The addresses of the Branch Registrars are:

General Medical Council, 44, Hallam Street, Portland Place London, W.1.
Scottish Branch Council, 12, Queen Street, Edinburgh.
Irish Branch Council, 35, Dawson Street, Dublin.

Examining Bodies in Preliminary Education.

The following is a list of the officials of the examining bodies in preliminary education, with the names of the examinations in parentheses.

Registrar, Queen's University of Belfast, Belfast. (Matriculation.)
Registrar, The University, Bristol. (Matriculation, School Certificate, or Higher School Certificate.)
Assistant Registrary, The University, Cambridge. (Previous.)
Secretary, Cambridge Local Examinations, Syndicate Buildings, Cambridge. (School or Higher School Certificate.)
Medical Registrar, University of Dublin School of Physic, Dublin. (Junior Freshman, Special Preliminary, Junior Exhibition, or Examination for first, second, third, or fourth year in Arts.)
Registrar, University of Durham College of Medicine, Newcastle-on-Tyne. (School or Higher School Certificate.)
Registrar, Irish Conjoint Board, Royal College of Surgeons, Dublin.

reland, Dublin. (Matriculation.)
Department of Education, 1, Hume
Examination or Leaving Certificate.)
Education, Belfast. (Senior Grade

ity of London, South Kensington, General, or Higher School Certificate.)
Secretary, Northern Universities Joint Matriculation Board, 315, Oxford Road, Manchester. (Matriculation, School, or Higher School Certificate.)
Registrar, University Registry, Oxford. (Responsions.)
Secretary, Oxford and Cambridge Schools Examination Board, Schools [illegible] College, Oxford. (School or Higher

University Press, Oxford. (School

Bloomsbury Square, London, W.C.2

Secretary, Educational Institute of Scotland, 47, Moray Place, Edinburgh. (Preliminary Medical Certificate.)
[illegible] partment, 14, Queen Street, Edinburgh.

Entrance Board, 61, North Street, St. Andrews. (Scottish Universities Entrance Examination.)
Registrar, University of Wales, Cathays Park, Cardiff. (Matriculation.)
Clerk, Central Welsh Board, Cardiff. (School or Higher School Certificate.)

[*Note*.—School Certificates other than "Higher" must show "Credits" in each of the prescribed subjects.]

Licensing Bodies.

The following is a list of the officials of licensing bodies and their addresses:

Secretary, English Conjoint Board, 8, Queen Square, Bloomsbury, W.C.1.
Clerk, Society of Apothecaries, Blackfriars, E.C.4.
Dean, Department of Medicine, Oxford.
Registrary, The University, Cambridge.
Registrar, University of Durham College of Medicine, Newcastle-on-Tyne
Principal Officer, University of London, South Kensington, S.W.7.
Registrar, Victoria University, Manchester.
Registrar, The University, Birmingham.
Registrar, The University, Liverpool.
Registrar, The University, Leeds.

Registrar, The University, Sheffield.
Registrar, The University, Bristol.
Registrar, University of Wales, Cathays Park, Cardiff.
Secretary, Scottish Conjoint Board, 49, Lauriston Place, Edinburgh.
Dean of the Faculty of Medicine, The University, Edinburgh.
Registrar, The University, Glasgow.
Registrar, Royal Faculty of Physicians and Surgeons, Glasgow (*Dental*)
Secretary of the Medical Faculty, The University, Aberdeen
Secretary, The University, St. Andrews.
Secretary, Irish Conjoint Board, Royal College of Surgeons, Dublin
Registrar, Apothecaries' Hall of Ireland, 95, Merrion Square, Dublin.
Medical Registrar, The University, Trinity College, Dublin.
Registrar, National University of Ireland, University College, Dublin.
Registrar, Queen's University, Belfast.

Medical Schools.

The following is a list of medical schools (other than universities) and their officials:

Registrar, College of Medicine, Newcastle-on-Tyne
Dean of the Medical College, St. Bartholomew's Hospital, London, E.C.1
Dean of the Medical School, Charing Cross Hospital, W.C.2.
Dean of the Medical School, St. George's Hospital, S.W.1
Dean of the Medical School, Guy's Hospital, S.E.1
Dean of the Medical School, King's College, Strand, W.C.2.
Dean of the Medical School, King's College Hospital, S.E.5
Dean of the Medical College, London Hospital, E.1.
Dean of the Medical School, St. Mary's Hospital, W.2
Dean of the Medical School, Middlesex Hospital, W.1
Dean of the Medical School, St. Thomas's Hospital, S.E.1
Dean of the Medical School, University College Hospital, W.C.1.
Dean of the Medical School, Westminster Hospital, S.W.1
Dean of the School of Medicine for Women, 8, Hunter Street, W.C.1.
*Registrar, University College, Aberystwyth.
*Registrar, University College, Bangor.
*Registrar, University College, Cardiff.
Dean of the Medical School, Welsh National School of Medicine, Cardiff.
Dean of the Medical School, University College, Swansea
Dean of the Medical School, University College, Dundee.
Dean, School of Medicine of the Royal Colleges, Surgeons' Hall, Edinburgh.
Dean, St. Mungo's College, Glasgow
Dean, Anderson's College of Medicine, Glasgow.
Mistress, Queen Margaret College, Glasgow.
Registrar, University College, Cork.
Registrar, University College, Dublin.
Secretary, School of Medicine, Royal College of Surgeons, Dublin.
Registrar, University College, Galway.
* First year only.

Professional Examination.

The Council's Recommendations.

The following recommendations of the General Medical Council in regard to professional examinations for medical and surgical qualifications were adopted in May, 1922:

1. In order to secure due continuity and sequence in medical study, two or more professional examinations in the earlier subjects should be held antecedently to the Final Examination in medicine, surgery, and midwifery.

2. Three years at least should intervene between the date of passing the professional examination in anatomy and physiology and that of admission to the Final Examination in medicine, surgery, and midwifery.

3. A candidate remitted in any subject of a professional examination should, before he is readmitted to examination therein, be required to produce satisfactory evidence that he has, during the interval of remission, pursued the study of the subject in which he was rejected. Candidates who obtain less than 30 per cent. of the marks in any subject should be remitted for a longer period than three months.

4. In all the professional examinations sufficient time should be assigned to practical work, in order to test the thoroughness of the candidate's knowledge and to encourage practical methods of study.

5. Candidates in all their examination work should be carefully supervised.

6. Two examiners should always participate in the oral examination of a candidate, except in subordinate parts of practical examinations.

7. In all written examinations the questions in each subject should be submitted for the approval of all the examiners in that subject.

8. In all written examinations an average of at least half an hour should be allowed for a candidate to answer each question.

9. It is desirable that examiners, and in particular those for the Final Examination in medicine, surgery, and midwifery, should be appointed or re-elected for at least three consecutive years.

10. Whatever may be the system of marking, the percentage for a pass in each subject should not be less than 50.

11. In the regulations for the several examinations it should be provided that examiners, in assessing marks, be empowered to take into account the duly attested records of the work done by the candidate throughout his course of study in the subject of the examination.

12. The Final Examination in medicine, surgery, and midwifery, with the exception of the clinical and practical examination in midwifery and gynaecology, must not be passed before the close of the fifth academic year of medical study.

13. The three portions of the Final Examination in medicine, surgery, and midwifery should not be further subdivided into sections which may be entered for or passed separately.

14. Compensation in respect of marks as between the three different portions of the Final or Qualifying Examination—namely, medicine, surgery, and midwifery—is contrary to the intention of the Medical Act (1886).

15. The Final Examination should include clinical and practical examinations in midwifery and gynaecology.

16. The clinical examination in medicine, surgery, and midwifery should be held in properly equipped hospitals or examination halls well provided with suitable patients.

17. In the examinations in clinical medicine at least one hour, and in clinical surgery at least half an hour, should be allowed to the candidate for the examination of, and report on, his principal case.

18. In medicine, in surgery, and in midwifery, no candidate should be allowed to pass who fails to obtain 50 per cent. of the aggregate marks assigned to the whole examination; or who fails to obtain 50 per cent. of the marks assigned to the clinical examination; or who fails to obtain 40 per cent. of the aggregate of the marks assigned to the written and oral examination. In midwifery, where a clinical examination is not held, the duly attested records of the work done by the candidate in clinical midwifery must be presented to the examiners for assessment in the Final Examination; and no candidate should be allowed to pass who fails to obtain 50 per cent. of the aggregate marks assigned to clinical and practical midwifery and gynaecology.

19. The Final Examination should include the examination of secretions, the testing of urine, clinical microscopy, and prescription writing, and there should always be an oral examination in medicine, surgery, and midwifery, which should include an examination on pathological specimens.

20. At the Final Examination each candidate should be submitted to a practical and oral examination in pathology (macroscopic and microscopic), unless this has been included in a professional examination preceding the Final Examination.

21. Whatever be the method of entry for the Final Examination all candidates should be required to complete the three portions of the Final Examination within a period of nineteen months.

This section of the Educational Number would be incomplete without brief mention of the memorandum, drawn up by the Registrar of the General Medical Council, on the procedure to be adopted by those who desire to enter the profession of medicine, to which reference is made in the introductory article at page 383. This pamphlet (price 1s. post free) sets out in plain language the information for which the Registrar is often asked by prospective medical students or their guardians.

The English Universities.

There are eleven universities in England and Wales, and some account of each of them follows. They all have now fully developed medical faculties. Until recently the only exception was the University of Wales, whose constituent colleges are those of Aberystwyth, Bangor, Cardiff, and Swansea. This university grants the degrees of M.B., B.Ch., and provision is now made at the Welsh National School of Medicine at Cardiff for instruction in all the subjects of the medical curriculum.

UNIVERSITY OF OXFORD.

The professional degrees conferred by this university are those of Bachelor of Medicine (B.M.), Bachelor of Surgery (B.Ch.), Doctor of Medicine (D.M.), and Master of Surgery (M.Ch.). It also grants a diploma in public health and a diploma in ophthalmology. On receiving the B.M. the candidate in entitled to registration by the General Medical Council. In favourable circumstances this degree and the B.Ch. may be obtained in six or seven years from matriculation. Before receiving either, the candidate must have taken a degree in arts (B.A.), for which three years' residence within the university is necessary. This, however, does not necessarily mean deferment of professional study for that period, for the subjects chosen for the arts course may be to a great extent the same as those in which examinations would in any case have to be passed for the medical degree, and the courses are dovetailed together.

In accordance with a statute which came into force on October 7th, 1920, women may be matriculated and admitted to degrees in the university. The statute is retrospective under certain conditions. Before matriculation a woman must have been admitted as a member of one of the

five societies of women students (Lady Margaret Hall, Somerville College, St. Hugh's College, St. Hilda's Hall, or the Society of Oxford Home Students). Women members of the university are admitted to all degrees, except those in divinity, under the same conditions as those laid down for men in regard to examinations, courses of study, and fees, and under corresponding conditions as to residence at the university. Among the university diplomas open to women are those in anthropology, ophthalmology, and public health.

There are numerous avenues to the B.A. degree, but that which constitutes the *normal* course for medical students, as being the most closely related to their medical studies, is the following: By passing Responsions (or one of the examinations which are accepted as equivalent), the Scripture examination, some of the preliminary examinations in the Natural Science School,[1] in the first public examination; and one of the final honour examinations in the Final Honour School of Natural Science—physiology being that usually taken.

Responsions and the preliminary examinations in natural science may be passed before a candidate is a member of the university[2]; a final honour school may be taken at the end of the third or fourth academical year—that is, within nine or twelve terms respectively; the preliminary examinations of the Natural Science School may be taken as soon as Responsions has been passed or exemption obtained.

PROFESSIONAL DEGREES.

To obtain the B.M., B.Ch. degrees the candidate must first pass in four of the subjects of the preliminary examination of the Natural Science School—namely, physics, chemistry, zoology, and botany.

He then has two further examinations to pass—the First B.M. and the Second B.M. These take place twice a year, the first on the Thursday, the second on the Wednesday, of the eighth week of Michaelmas and Trinity terms. Every candidate at the first B.M. is examined in human anatomy, in physiology, and in organic chemistry, but is excused from physiology if he has obtained a first or second class in the Honour School of Physiology, and from organic chemistry if he has satisfied the examiners in Part I of the Honour School of Chemistry. Once he has passed this examination he can, on production of certain certificates, be examined as soon as he pleases in pathology, forensic medicine and hygiene, materia medica, and pharmacology (subjects of the second examination), but cannot present himself for the remaining subjects—medicine, surgery, and midwifery—until the eighteenth term from the day of his matriculation *unless he be already a registered medical practitioner*, and not until a period of at least thirty-three months has elapsed from the date of his passing the first examination, and he must pass in all the three subjects at one and the same time.

Before admission to the Second B.M. examination the student must produce certificates of instruction from a medical school recognized by the university, of having acted as clinical clerk and dresser, each for six months, and as post-mortem clerk for three months, of attendance on labours, of instruction in infectious and mental diseases and ophthalmology, and of proficiency in vaccination and the administration of anaesthetics,[3] and of three academic years of hospital attendance. He must also produce certificates of attendance in laboratory courses in pathology, bacteriology, and pharmacology, either in Oxford or in a recognized medical school.

D.M. AND M.CH. DEGREES.

A Bachelor of Medicine who wishes to proceed to the D.M. must have entered his thirtieth term and must present a dissertation for approval by the appointed examiners on a subject previously approved by the Regius Professor of Medicine. If a candidate for the M.Ch. he must have entered his twenty-first term and must pass an examination, which is held in June.

[1] The four subjects of the medical preliminary examinations are four of the subjects in the natural science preliminary, and can be commenced directly after passing Responsions.

[2] Membership is constituted by Matriculation and by becoming either a member of a College or a Hall or a non-collegiate student.

[3] For the certificates that will be required from candidates amenable to the new Regulations of the General Medical Council, see *Examination Statutes*, Clarendon Press, Oxford, 1925 edition.

D.P.H. AND D.O.

Examinations for the diploma in public health have been suspended until further notice; that for the diploma in ophthalmology is held annually in March.

TEACHING.

The several colleges provide their undergraduate members with tutors for all examinations up to the B.A. degree. In addition, the university provides certain courses of instruction, including lectures, demonstrations, and practical work, which cover all the subjects of the Preliminary Examination and First B.M., and those of the Final Examination.

SCHOLARSHIPS.

Most colleges grant scholarships open to intending medical students of the maximum value of £100 a year, tenable for four years, in natural science, chemistry, physics, and biology. Exhibitions of varying value are also awarded in these subjects. At two colleges (University and Pembroke) there are medical entrance scholarships of £100 a year. Particulars can be obtained on application to the college tutors. Scholarships for women are also offered by the various women's colleges, from the principals of whom details of the examinations may be obtained. A Radcliffe Travelling Fellowship of £300 a year, tenable for two years, is conferred annually; candidates must have taken the B.M. degree. A Schorstein Research Fellowship of £200 a year for two years is awarded biennially. The Fellow must engage in research in one of the Medical Departments of the University. A George Herbert Hunt Travelling Scholarship of about £100 is awarded biennially to enable a young medical graduate to spend three months abroad in medical study. A Philip Walker Studentship in Pathology of £200 a year, tenable for two years, is awarded biennially for the encouragement of research in pathology, as also are the Rolleston Memorial Prize and the Radcliffe Prize (£50), for research in natural science (including pathology), and the three Theodore Williams Scholarships in Anatomy, Physiology, and Pathology, of the value of £50 each, tenable for two years. A Radcliffe Scholarship in Pharmacology of £50 for one year, open to the University, is awarded annually by the Master and Fellows of University College. A Burney Yeo King's College Hospital Scholarship of £80 is awarded annually.

FEES.

An annual fee of £4 10s. is paid to the university for the first four years, being reduced to £1 when the B.A. has been taken. For the degree the fees are: the B.A., £7 10s.; the B.M. and B.Ch., £14; the D.M., £25; the M.Ch., £12. College fees, varying in amount, are paid for the first four years of membership and in taking degrees. Tuition fees vary from £21 to £30. The minimum annual cost of living during the three university terms may be regarded as not less than £200, or for women not less than £140.

For further information application may be made to Dr. E. W. Ainley Walker, Dean of the School of Medicine, University of Oxford.

UNIVERSITY OF CAMBRIDGE.

THE professional degrees given by this university are those of Bachelor of Medicine (M.B.) and Bachelor of Surgery (B.Chir.), each of which entitles the possessor to admission to the *Register* by the General Medical Council, and the higher degrees of Doctor of Medicine and Master of Surgery. It also grants diplomas in tropical medicine and hygiene, in public health, in hygiene, and in medical radiology and electrology to medical practitioners, not necessarily graduates of the university. Information regarding these diplomas will be found in later sections under the headings Tropical Medicine, Public Health, and Radiology. A candidate for the M.B., B.Chir. degrees need not possess a degree in arts; it is sufficient if he has passed the Previous examination or some other examination accepted by the university as its equivalent. Most students, however, are advised to take the B.A. degree, preferably by obtaining honours in the Natural Science Tripos at the end of their third year. The attainment of a sufficient standard in certain subjects in this Tripos will secure exemption from the corresponding tests in the First and Second M.B. examinations in the case of students who take up medical study late in their university career. Members of Girton College and Newnham College are admitted to the M.B. examinations.

PROFESSIONAL EXAMINATIONS.

To obtain the M.B. degree the candidate must pass three examinations and keep an Act. The B.Chir. degree (which is a registrable qualification) may be obtained after passing all three examinations.

First M.B.—This comprises (1) general and inorganic chemistry, (2) mechanics, (3) physics, (4) elementary

biology. The parts may be taken together or separately. In either case the candidate, before admission to examination, must have passed or been exempted from the Previous examination. Certain exemptions from the First M.B. Examination are allowed: the regulations may be obtained from the Registrary. The examination is held three times in the year.

Second M.B.—This examination comprises: Part I, organic chemistry; Part II, human anatomy and physiology; Part III, elementary pharmacology, including pharmaceutical chemistry and the elements of general pathology. No student is admitted to the first part of the Second Examination until he has passed the first part of the First Examination. No student is admitted to the second part of the Second Examination until he has passed all parts of the First Examination. No student shall be admitted to the third part of the Second Examination until he has passed the first and second parts of the Second Examination. The candidate must present certificates of study in the subjects of the second and third parts. The examinations for Part I are held in October, December, and June, and for Part II in December and June; that for Part III in October and April.

Third M.B.—This is divided into two parts, to neither of which the candidate is admitted until he has passed the examinations previously mentioned. A candidate for the first part, which deals with the principles and practice of surgery (including special pathology) and midwifery and diseases peculiar to women, must have completed five years of medical study and be signed up in these subjects and have completed two years and a half of hospital practice. Before admission to the second part the candidate must have completed five years of medical study, and be duly signed up in all subjects and have completed three years of hospital practice. The examination is in the principles and practice of physic (including diseases of children, mental diseases, and medical jurisprudence), pathology (including hygiene and preventive medicine), and pharmacology (including therapeutics and toxicology). The Third M.B. examinations are held twice a year—in June and December.

Act for the M.B.—Before receiving his M.B. degree a candidate who has passed the Third M.B. examinations has to write a thesis. This he reads in public on an assigned day, and is then questioned concerning it and other subjects of medicine by the Regius Professor of Physic. If approved at this test he is then certified as having "kept the Act" satisfactorily, and in due course receives his degree. Medical degrees may be taken in absence by those living abroad, the candidate sending to the Registrary a dissertation, which is laid before the Degree Committee.

The Higher Degrees.

The M.D. degree may be taken by a Bachelor of Medicine of three years' standing (and a Master of Arts of four years' standing who has completed the course required for M.B.) after writing a thesis approved by the M.D. Degree Committee, and keeping a further Act, at which he reads his thesis and is examined thereon. Previously to the Act being kept a topic taken from the general subject of his thesis (whether it be physiology, pathology, pharmacology, practice of medicine, State medicine, or the history of medicine) is submitted to the candidate, on which he is required to write an extempore essay.

A candidate for the M.Chir. degree who is an M.A. may be admitted to the examination after he has become legally qualified to practise surgery. Other candidates may be admitted when two years have elapsed after they have passed the Third M.B. Examination. The examination comprises pathology, surgery, surgical anatomy, and surgical operations. The tests are partly in writing, partly oral, and partly practical: they include the writing of an extempore essay. The examination is held in June and December.

Fees.

In addition to college fees, tutorial fees, and the expense of living, the following examination fees are payable: First M.B., £5 5s.; Second M.B., £6 6s.; Third M.B., £10 10s. For schedules referring to the examinations, lists of schools recognized by the university, and other information, application should be made to the University Registrary, Cambridge.

UNIVERSITY OF LONDON.

Under the regulations of the University of London the degrees obtainable in the Faculty of Medicine are those of Bachelor of Medicine and Surgery, Master of Surgery in four branches, Doctor of Medicine in six different branches, Bachelor of Dental Surgery, and Bachelor of Pharmacy. The university has its own matriculation examination, and this is of so peculiar a kind that candidates should obtain and carefully study the booklets relating to it. The matriculation examination is open to any person, of either sex, who has attained the age of 16. It is held in January, June, and September, and lasts four days; the first two take place both in London and in certain provincial centres; the September examination is held in London only.

In no circumstances is a degree granted to anyone in less than three years after the date at which he passed the matriculation examination or obtained registration in some other way; and, unless they are already registered medical practitioners of a certain age and standing, all medical students must pass not less than five and a half years in professional study subsequent to matriculation, of which the last three years must be spent at a school of advanced medical studies.

Professional Examinations.

M.B., B.S.—There are three examinations, the last two being subdivided. They are held twice a year.

The First Examination (held in July and December) covers inorganic chemistry, general biology, and physics, there being two papers, a practical test, and a possible oral test in each subject. The names of successful candidates are placed in alphabetical order with a note as to any subject in which a candidate has distinguished himself or herself.

The Second Examination is held in March and July. Part I cannot be passed within six months of the passing of the First Examination. It covers organic chemistry, the candidate's knowledge being tested as in the earlier examination. Candidates for Part II must have passed the First Examination at least eighteen months previously, besides having completed Part I of the Second Examination. The subjects are anatomy, physiology, and pharmacology, the tests being written, oral, and practical. Candidates who fail in one subject may sit for re-examination in that subject alone if the examiners think fit.

No candidate is admitted to the Third M.B., B.S. Examination within three academic years from the date of his completing the Second Examination. The subjects are medicine (including mental diseases), pathology, forensic medicine and hygiene, surgery, and obstetrics and gynaecology. They may be divided into two groups, one comprising medicine, pathology, forensic medicine, and hygiene, and the other surgery and obstetrics and gynaecology. Either group may be taken first at the option of the candidate, or the groups may be taken together. Only candidates who show a competent knowledge of all the subjects comprising a group are passed. There is no separate examination held for honours, but the names of successful candidates are divided into an honours list and a pass list, and a university medal may be awarded the candidate who has most distinguished himself in the whole examination.

The Higher Degrees.

M.D.—An examination for the M.D. is held twice yearly—in December and July. Every candidate must have passed the examination for the M.B., B.S., unless he became M.B. before May, 1904. He may present himself for examination in any one of the following branches: (1) medicine, (2) pathology, (3) mental diseases and psychology, (4) midwifery and diseases of women, (5) State medicine, (6) tropical medicine, and, if he wishes, may pass also in another branch at a subsequent examination.

The period that must elapse between acquiring the M.B. and sitting for the M.D. in any branch varies between one and two years, according to the nature of the candidate's previous work, and in all cases evidence must be afforded of special study of the subject chosen; both written and practical examinations must be passed, though exemption can be obtained from the former in exceptional circumstances. In each branch the scheme of examination is

the same: two papers on its special subject, a paper on an allied subject—for example, medicine in the case of branch (4), pathology in branch (1)—an essay on one of two suggested topics connected with the special subject, and a clinical or other practical test. In any branch of the M.D. Examination a gold medal of the value of £20 may be awarded.

M.S.—The regulations with regard to the Mastership in Surgery are of a corresponding kind, but there are four branches in which it may be obtained—general surgery, dental surgery, ophthalmology, and laryngology, otology, and rhinology.

FEES.

For Matriculation: 2½ guineas for each entry. First Examination: 6 guineas for each entry to the whole examination. For re-examination in one subject the fee is 2 guineas. Second Examination, Part I: 3 guineas for the first and each subsequent entry. Second Examination, Part II: 9 guineas for each entry to the whole examination. For re-examination in one subject the fee is 4 guineas. M.B., B.S. Examination: 12 guineas for each entry to the whole examination, and 6 guineas for examination or re-examination in either group. M.D. and M.S. Examinations: 20 *guineas, and 10 guineas on re-examination.*

Inquiries should be addressed to the Academic Registrar, the University of London, South Kensington, S.W.7.

UNIVERSITY OF BIRMINGHAM.

THIS university confers medical and surgical degrees—namely, M.B., Ch.B., M.D., and Ch.M.—and also diplomas and degrees in State Medicine and dentistry. The M.B., Ch.B. candidate may also combine with the earlier part of his medical curriculum courses leading to the ordinary B.Sc. degree in anatomy and physiology. The degree of B.Sc. with honours in one of these subjects requires an extra year. The full course of study for the degrees of M.B., Ch.B. extends over six years. The Senate has power to accept courses of study and examinations passed at other recognized universities as exempting from the examinations in physics, chemistry, biology, and organic chemistry. In the case of such students at least three years must be spent in attendance upon classes at the university. A degree of Ph.D. is also conferred for research study in medicine under special regulations. Candidates must be graduates in medicine of a recognized university.

Students entering the Medical Faculty for the M.B., Ch.B. degrees must have passed—

(1) Either (*a*) the matriculation examination of the Joint Board of the Universities of Manchester, Liverpool, Leeds, Sheffield, and Birmingham; or (*b*) some other examination recognized as equivalent to the matriculation. Candidates for medical degrees are required to have passed in English literature and mathematics, and are recommended to take Latin and a science subject—chemistry or physics—at the matriculation examination. The matriculation examination of the Joint Board is held in July and September. The regulations and the list of examinations accepted in lieu thereof will be sent on application to the Secretary to the Board, *Joint Matriculation Board, 315, Oxford Road,* Manchester.

(2) A recognized pre-registration examination in the subjects of chemistry and physics—for example, the higher school certificate of the Joint Matriculation Board; or a candidate may attend first-year courses in the university, October to June, taking chemistry and physics, and biology.

For and after the session 1929–30 the passing of an examination in elementary biology will be compulsory before a student reading for the M.B., Ch.B. Birmingham, or for any medical or dental degree or diploma in which an examination has to be passed in this subject, can enter the Faculty of Medicine.

PROFESSIONAL EXAMINATIONS.

The candidate for the M.B., Ch.B. degrees has five examinations to pass. In the Second (Part II) and Final examinations the candidate must pass in all the prescribed subjects or undergo the whole examination again.

The First M.B. deals with physics, chemistry, and biology. The Second M.B. (Part I) deals with organic chemistry. The Second M.B. (Part II) deals with anatomy and physiology, and the student must pass in both simultaneously. The Third M.B. deals with pathology and bacteriology. The Fourth M.B. takes place at the end of the fifth year, the subjects being forensic medicine, toxicology, public health, and pharmacology and therapeutics.

Final M.B.—This comprises medicine, surgery, midwifery and diseases of women, ophthalmology, and mental diseases. The candidate, in addition to more ordinary certificates, must be prepared with a certificate of having acted as a post-mortem clerk for three months, and received special instruction in anaesthetics and clinical instruction in diseases peculiar to women, asylum ward work, ophthalmology, children's diseases, venereal diseases, ear and throat and skin diseases, etc. In respect to ophthalmology he must show that he has learnt refraction work. He also has to present to the examiners at the time of his examination a short written commentary on a gynaecological subject or case investigated during the period of gynaecological clerking, and certificates drawn up by himself regarding four actual cases of lunacy and notes on two others.

M.D.—An ordinary candidate for this degree must be a M.B., Ch.B. of not less than one year's standing. He presents an original thesis for approval, and then passes a general examination in the principles and practice of medicine. From the latter the Board of Examiners may exempt a candidate whose thesis is of exceptional merit. The regulations respecting the Ch.M. are of the same general character. Subject to certain requirements as to special research or other post-graduate study, graduates of other universities may obtain the M.D. and Ch.M. in the same way as holders of the Birmingham M.B., Ch.B.

FEES.

The fee for Matriculation is £2 (payable to Joint Matriculation Board); £2 10s. for Pre-Medical Examination (if taken in university), and £2 10s. for each of the first four Professional Examinations; M.B., Ch.B. degree fee, £10; M.D. and Ch.M. Examinations, £12 10s. each. For further particulars application should be made to the Dean of the Medical Faculty, University of Birmingham.

UNIVERSITY OF BRISTOL.

IN the Faculty of Medicine the following degrees are conferred: Bachelor of Medicine and Bachelor of Surgery (M.B. and Ch.B.), Doctor of Medicine (M.D.), Master of Surgery (Ch.M.), Bachelor of Dental Surgery (B.D.S.), and Master of Dental Surgery (M.D.S.). There are also the following diplomas: diploma in public health (D.P.H.), diploma in dental surgery (L.D.S.), and diploma in veterinary State medicine. All candidates for degrees in medicine, surgery, and dentistry are required to reach matriculation standard in the school certificate examination, or to pass such examination as may be regarded as equivalent by the Senate. All courses, degrees, and diplomas are open to men and women alike.

Conjoined Degrees of Bachelor of Medicine and Bachelor of Surgery.—Candidates must be not less than 21 years of age and have pursued the courses prescribed by university regulations during not less than five years after passing the first examination in chemistry and physics, of which three shall have been spent in the university, and two of these three subsequent to passing the second examination. All candidates for the degrees of M.B., Ch.B. are required to satisfy the examiners in the several subjects of three examinations.

The First Examination.—The subjects of examination are: chemistry (inorganic), physics, and biology, the courses pursued being those for the time being approved for the intermediate part of the B.Sc. curriculum. This part of the curriculum shall extend over one year. (Candidates who have passed the higher school certificate approved by the Board of Education in these subjects will not be required to sit for the First Examination and will be regarded as having completed one year of study.)

The Second Examination.—The subjects of examination are: organic chemistry and elementary anatomy (Part I) and advanced anatomy and physiology (Part II).

The Final Examination.—The subjects of examination are: materia medica and pharmacy, pharmacology and therapeutics, general pathology, morbid anatomy, and bacteriology (Part I); special pathology, forensic medicine, toxicology, and public health, obstetrics (including

diseases of women), surgery (systematic, clinical, practical, and operative, including ophthalmology and oto-rhino-laryngology), medicine (systematic, clinical, and practical, including mental diseases) (Part II). The subjects included in Part II may be taken in two groups—namely, Group I: surgery and obstetrics; Group II: medicine, public health, special pathology, forensic medicine, and toxicology. Candidates may pass Parts I and II together or separately, and the two groups of Part II may likewise be taken together or separately, but no student can obtain honours who elects to take the two groups of Part II separately. *Forensic medicine and toxicology may be taken either with* Part I or with Group II of Part II.

Degree of Doctor of Medicine.—Candidates must be Bachelors of the university of not less than two years' standing as such, and may elect either (1) to pass an examination in general medicine, or (2) to pass an examination in State medicine, or (3) to present a dissertation. The candidate who elects to pass the examination in State medicine must hold a diploma in public health of some university or college, and the candidate who elects to present a dissertation may be examined in the subject thereof.

Degree of Master of Surgery.—Candidates shall be Bachelors of not less than two years' standing as such, during which period they shall have attended the surgical practice of an institution approved for the purpose. They shall pass an examination in surgical anatomy, pathology, and bacteriology, and operative, clinical, and general surgery, and present to the university a dissertation on some subject of surgery. The degree may be taken also in general surgery, and a special subject—for example, oto-rhino-laryngology, ophthalmology, and gynaecology.

Diploma in Public Health.—Candidates must be at least 23 years of age, be fully registered medical practitioners of not less than two years' standing as such, and have passed the examination prescribed by regulation. The examination is divided into two parts.

UNIVERSITY OF DURHAM.

To its own undergraduates, who may be of either sex, this university grants the degrees of Bachelor of Medicine and Bachelor of Surgery (M.B., B.S.), and Doctor of Medicine (M.D.), Master of Surgery and Doctor of Surgery (M.S. and D.Ch.), Bachelor of Hygiene, Doctor of Hygiene, and Bachelor of Dental Surgery and Master of Dental Surgery (B.D.S. and M.D.S.); it also grants diplomas in public health, psychiatry, and dental surgery. The university accepts the Durham University school certificate examination (if a sufficient standard is obtained in certain specified subjects) for matriculation purposes, but also accepts the tests of a considerable number of other educational bodies as a full or partial equivalent. A list may be obtained on application. In addition to satisfying the matriculation requirements of the university, every student must (1) pass a pre-registration examination in physics and inorganic chemistry conducted or recognized by the university, and (2) be registered on the books of the General Medical Council. To become a graduate, however, at the university it is not necessary to pass the major portion of the five years' curriculum within its precincts. It is sufficient if, before he presents himself for his final examination, the candidate has spent at least one year in study at the University of Durham College of Medicine, Newcastle-on-Tyne, including the practice of the Royal Victoria Infirmary in the same city. The earlier examinations may be passed while the student works elsewhere.

PROFESSIONAL EXAMINATIONS.

There are four professional examinations for the M.B., B.S. degrees. The First, Second, and Third examinations are held in March and June, and the Final Examination in June and December. The first deals with biology and organic chemistry; the second with anatomy and physiology; the third with pathology, bacteriology, materia medica, pharmacology, general principles of therapeutics, and pharmacy, medical jurisprudence, and public health. At the Final M.B., B.S. the candidate is examined in medicine and clinical medicine; surgery and clinical surgery; midwifery and diseases of women and children; clinical and practical midwifery and gynaecology; and clinically in psychological medicine, diseases of the throat, nose and ear, diseases of the skin, diseases of the eye, and diseases of children.

M.D.—A Bachelor of Medicine who wishes to proceed to this higher degree must be of at least two years' standing, and must comply with the regulations printed in the Calendar of the College of Medicine. If the candidate is not an M.B. of the university, he must be a practitioner of fifteen years' standing, 40 years of age, and submit to special tests. (See under Degrees for Practitioners, p. 438.)

M.S.—Candidates for this degree must have been engaged in practice for at least two years subsequent to becoming M.B., B.S. Durham. They are submitted to an examination which covers the whole range of surgical knowledge.

D.Ch.—The university grants also the degree of Doctor of Surgery. Candidates for this degree must be registered medical practitioners, not less than 24 years of age. They must devote three years, subsequent to obtaining a registrable qualification, to the study of surgery and ancillary subjects; one at least of the three years must be spent in the university. The candidate must submit to the professor of surgery the course of study he proposes to follow, and this course must be approved by the Board of Faculty of Medicine.

One year must be devoted mainly to work in the departments of anatomy, physiology, pathology, and bacteriology, and the candidate must submit evidence of having so worked. Not less than six months of another year must be spent as a resident surgeon in a recognized teaching hospital, and the rest of the year in the study of surgery in a recognized medical centre. Not less than six months of one of the three years must be spent in surgical study abroad.

Degree of Bachelor of Hygiene and the D.P.H.

No candidate is admitted to the final examination for the degree of B.Hy. unless he is a Bachelor of Medicine and Surgery, of not less than two years' standing, of a recognized university whose degrees are registrable on the books of the General Medical Council of the United Kingdom.

No candidate is admitted to the final examination for the D.P.H. unless he is a registered medical practitioner of not less than two years' standing.

The course of study for the B.Hy. and D.P.H. extends over a period of not less than twelve calendar months subsequent to the attainment of a qualification registrable by the General Medical Council of the United Kingdom. Candidates for the B.Hy. must attend this course at the University of Durham; candidates for the D.P.H. may attend it at the University of Durham or at any medical school or institution which is recognized by the university.

The examination for the diploma or degree consists of Part I and Part II, each of which extends over not less than two days, and is conducted by examiners specially qualified. A candidate must pass in all the subjects of Part I before being admitted to examination for Part II. In Part I, and also in Part II, a candidate must pass in all the specified subjects at one time.

The [illegible] for Part I is practical, written, and oral, and includes [illegible] bacteriology and parasitology (includ[illegible] chemistry and physics; and meteor[illegible] relation to public health. Candidates are not admitted to examination for Part I until after they have completed the prescribed courses of instruction in the subjects thereof.

The examination for Part II includes the following subjects: hygiene and sanitation (including sanitary construction); epidemiology and infectious diseases; sanitary law and vital statistics; public health administration. The examination is written and oral, and includes practical examinations in infectious diseases; food inspection, inspection of premises—dwellings, factories, workshops, schools, etc. Candidates are not admitted to examination for Part II until after they have completed the prescribed courses of instruction in the subjects thereof.

Doctor of Hygiene.

Candidates for the degree of Doctor of Hygiene must be Bachelors of Hygiene of the university of two years' standing, and are required to satisfy the examiners that they have conducted original research in the subject of public health.

Diploma in Psychiatry.

Candidates must be registered medical practitioners, and, unless qualified before January 1st, 1911, must have attended, subsequent to passing their qualifying examinations, courses of instruction in: (*a*) anatomy; (*b*) physiology; (*c*) pathology; (*d*) bacteriology; (*e*) psychology and experimental psychology; (*f*) clinical neurology; (*g*) psychiatry; (*h*) clinical psychiatry, [illegible] physiology; (2) psychiatry [illegible] themselves f[illegible]y.

Licence and Degrees in Dental Surgery.

L.D.S.—Every dental student must, at the commencement of his studentship, be registered in the manner and under the conditions prescribed for medical students.

The First Examination consists of three parts, which may be passed separately: Part 1, organic chemistry; Part 2, biology; Part 3, theoretical dental mechanics, dental metallurgy (theoretical and practical). Second Examination: Anatomy, physiology (including biochemistry and biophysics), dental anatomy, and dental histology. Third Examination: Pathology and bacteriology, practical dental mechanics, dental materia medica and therapeutics. Final Examination: Medicine, surgery, dental surgery and pathology, orthodontics, operative dental surgery and dental prosthetics, and anaesthetics.

A candidate before presenting himself for examination is required to furnish certificates of instruction in the required subjects, attended after registration as a dental student at recognized colleges or medical schools.

Degree of Bachelor of Dental Surgery.—1.—Students taking their complete course of instruction in the university must pass the same matriculation tests as medical students, and the same pre-registration examination in inorganic chemistry and physics. After registration students must spend five years in the university. They must attend the practice of the Newcastle-upon-Tyne Dental Hospital for not less than two and a half years; six months of this time must be devoted to the study of the higher branches of dental science. There are four examinations. The subjects of the examinations are as follows: *First:* Biology, organic chemistry, and dental mechanics and metallurgy. *Second:* Anatomy, physiology, dental anatomy, and histology. *Third:* Pathology and bacteriology, dental materia medica and therapeutics, and practical and dental mechanics. *Final:* Medicine, surgery, dental surgery and pathology, orthodontics and operative dental surgery. In this subject knowledge of a much higher standard, and more advanced practical work, are required than for the Licence in Dental Surgery.

2. Candidates obtaining a Licence in Dental Surgery of a [illegible] study for at least one year in the [illegible] year they must (*a*) attend a course of [illegible] and bacteriology, and (*b*) spend at [illegible] Newcastle-upon-Tyne Dental Hospital in the study and practice of the higher branches of dental science. They must also pass the third and final examinations for the degree of Bachelor of Dental Surgery.

Degree of Master of Dental Surgery.—Every candidate for this degree must be a Bachelor of Dental Surgery of the university of not less than two years' standing, and present an essay embodying original work and research in some subject connected with dentistry. He must also perform to the satisfaction of the examiners a piece of special dental work demanding a high degree of skill and experience.

The examinations are held concurrently with the medical examinations.

The practical examinations in dentistry are conducted at the Newcastle-upon-Tyne Dental Hospital.

FEES.

The following fees are payable: Matriculation, £2; Examinations, First, Second, and Third M.B., B.S., each £5; Final M.B., B.S., £15; M.D. and M.S., each £5; B.Hy., D.P.H., and D.Psy. each £10 10s., and D.Hy. and D.Ch. each £20; First, Second, and Third L.D.S., each £3 10s., and Final L.D.S. £5; First, Second, and Third B.D.S., each £5, Final B.D.S. £8; and M.D.S. £5. For degrees and diplomas: M.B., B.S., B.Hy., and B.D.S., each £6 6s. *plus* the sum of 10s. if it is the initial degree taken in the university; M.S. and M.D.S., each £6 6s.; M.D., D.Ch., and D.Hy., each £10; D.P.H., D.Psy., and L.D.S., each £3.

Further information may be obtained from the Dean of the College, University of Durham College of Medicine, Newcastle-on-Tyne.

UNIVERSITY OF LEEDS.

THE degrees granted in the Medical Faculty of this university are Bachelor of Medicine, Bachelor of Surgery (M.B. and Ch.B.), and Bachelor of Dental Surgery (B.Ch.D.), Doctor of Medicine (M.D.), Master of Surgery (Ch.M.), and Master of Dental Surgery (M.Ch.D.). It also gives diplomas in public health, in psychological medicine, in dental surgery, and in nursing.

Candidates for the M.B. must have attended courses of instruction approved by the university for not less than five years, two at least of such years having been passed in the university, at least one year being subsequent to the date of passing the first examination. They must also have matriculated by satisfying the examiners in:

I. *Either* English Composition and English Literature, *or* English Composition and History.

II. *Either* Mathematics *or* Latin.

III. } *Three* other subjects not already taken under I and II above,
IV. } chosen from the following list:

(1) English literature; (2) History; (3) Geography; (4) Greek; (5) Latin; (6) French; (7) German; (8) Some one other language approved by the Board; (9) Mathematics; (10) Mechanics; (11) Physics; (12) Chemistry; (13) General experimental science; (14) Natural history; (15) Botany.

Provided that (*a*) candidates who take Mathematics under II above must include one of the subjects 4—8; (*b*) candidates who take Latin under II above must include one of the subjects 9—15. In all cases Mathematics is a compulsory subject for admission to the Faculty of Medicine.

Exemption from the examination may be granted to applicants holding certificates of having passed examinations of a standard deemed by the Matriculation Board to be at least equal to the Board's examination.

PROFESSIONAL EXAMINATIONS.

The examinations for the M.B., Ch.B. number three. The first deals with (1) physics and chemistry, (2) biology. In each subject laboratory work is included, but the two parts can be taken separately. For neither can the candidate present himself until after matriculation and a period of approved work in the respective subjects.

The Second Examination.—The Second Examination consists of: Part I, organic chemistry; Part II, materia medica and practical pharmacy; Part III, anatomy and physiology. Candidates will be allowed to pass any parts separately.

The Final Examination.—The Final Examination consists of: Part I, pharmacology and pathology and bacteriology; Part II, medicine, surgery, obstetrics, gynaecology, and clinical pathology; Part III, forensic medicine, public health, and therapeutics. Part I may be taken at the end of the second clinical year, and must be passed before Parts II and III are taken. Parts II and III may be taken at the end of the third clinical year but not before the completion of the fifth year of medical study. If taken separately Part II must be passed before Part III.

M.D.—Candidates for this degree must be bachelors of medicine and bachelors of surgery of the university, and subsequently to having graduated must have completed two years of hospital practice or special study approved by the university; or four years in the practice of their profession in one or other of its various branches; six months' hospital practice or special study to count as the equivalent of one year's ordinary practice. Any subject except surgery of the medical curriculum may be chosen for the examination, but a thesis, the title of which must previously receive the approval of the Board of the Faculty of Medicine, may be submitted, and if it is adjudged to be of exceptional merit the candidate may be exempted from further examination.

Ch.M.—The candidate for this degree must have been admitted to the M.B., Ch.B. of the university not less than a year previously, and during that time must have held for at least six months a surgical appointment in a public institution affording full opportunity for the study of practical surgery. He must also have attended certain courses, including one on ophthalmology and one on bacteriology; he is then examined on the subject of surgery in all its branches.

FEES.

The Matriculation fee is £2, and on readmission £1 10s. For each of the other examinations £6 and £6 on readmission; Ch.M. £10 and same on readmission; M.D. £10. On conferment of the degree of Ch.M. £5 is payable, and £5 for the M.D. degree.

UNIVERSITY OF LIVERPOOL.

THIS university, besides granting degrees in medicine (M.B. and M.D.) and in surgery (Ch.B., M.Ch.Orth., and Ch.M.) gives degrees in dental surgery (B.D.S. and M.D.S.), a degree in hygiene (M.H.), and degrees in veterinary science (B.V.Sc., M.V.Sc., and D.V.Sc.). Diplomas are awarded in dental surgery (L.D.S.), tropical medicine (D.T.M.), tropical hygiene (D.T.H.), public health (D.P.H.), veterinary hygiene (D.V.H.), and medical radiology and electrology (D.M.R.E.). The degree of Doctor of Philosophy (Ph.D.) may also be taken in the Faculty of Medicine.

MATRICULATION.

The matriculation examination is governed by the Joint Matriculation Board, 315, Oxford Road, Manchester, which accepts, under certain conditions, the tests of several other bodies as its equivalent. Candidates will be required to

have included mathematics among the subjects in which they have passed at such examination.

It should be particularly noted that important alterations in regard to matriculation requirements and the first year's courses of study will come into operation in October, 1929. Particulars may be obtained on application to the Dean.

PROFESSIONAL EXAMINATIONS.

Candidates for the M.B., Ch.B. degrees have three examinations to pass, the first including (1) chemistry, (2) biology (zoology and botany), (3) physics, (4) special chemistry.

Second M.B.—This test covers (*a*) (1) anatomy, (2) physiology, including physiological chemistry and histology; and (*b*) (3) elementary bacteriology, (4) clinical chemistry, (5) general pathology. Candidates may present themselves in (*a*) and (*b*) separately.

Final M.B.—The subjects of the Final Examination are: (*a*) (1) special pathology and morbid anatomy, (2) forensic medicine and toxicology, (3) public health, (4) pharmacology and general therapeutics; (*b*) (5) obstetrics and diseases of women, (6) surgery—systematic, clinical, operative, and practical—including ophthalmology, (7) medicine—systematic and clinical—including therapeutics, mental diseases, and diseases of children. Candidates may take Parts (*a*) and (*b*) separately, but Part (*b*) may not be taken until five years of study have been completed.

M.D.—May be conferred on graduates (M.B., Ch.B. Liverpool) (*a*) on candidates of two years' standing who present a thesis acceptable to the Faculty, together with, if candidate desires, copies of published original papers upon medical science—oral examination on subject of thesis; (*b*) on candidates of five years' standing by examination.

Ch.M.—May be conferred on graduates (M.B., Ch.B. Liverpool) after examination. Other information concerning the diplomas of this university and its medical school will be found on page 413.

FELLOWSHIPS, SCHOLARSHIPS, AND EXHIBITIONS.

The university awards Fellowships annually to students of distinguished merit, as follows:

(1) John Rankin Fellowships in Anatomy; two, each of the value of £120, tenable for two years. (2) Ethel Boyce Fellowship in Gynaecology, value £100 and tenable for one year, open to fully qualified medical students of either sex. (3) John W. Garrett International Fellowship in Bacteriology, value £100 and tenable for one year. (4) Robert Gee Fellowship in Human Anatomy, value £100 and tenable for one year. (5) Holt Fellowships in Physiology and Pathology, two in number, value £150 each and tenable for one year. (6) Johnston Colonial Fellowship in Biochemistry, value £100 and tenable for one year. (7) Thelwall Thomas Fellowship in Surgical Pathology, value £150 and tenable for one year. (8) Lady Jones Fellowship in Orthopaedic Surgery, one, value £200, offered every two years.

There are, in addition, scholarships and exhibitions open to medical students.

VICTORIA UNIVERSITY OF MANCHESTER.

THIS university grants the four ordinary degrees in medicine and surgery—M.B. and Ch.B. and M.D. and Ch.M.; a degree and diploma in dental surgery; a diploma in public health; a certificate in factory and in school hygiene; a diploma in psychological medicine; and a diploma in bacteriology. Candidates for degrees must pass the special matriculation examination prescribed by the Faculty of Medicine (or some equivalent examination accepted in lieu thereof; see the prospectus of the Joint Matriculation Board), and study at the university itself for at least two years of the six years' curriculum, subsequent to the passing of the First M.B. Examination. The matriculation examination comprises (1) Latin, (2) mathematics, (3) the English language, its literature and history, (4) mechanics, (5) one subject at choice as approved by the Joint Board. It is held in July and September.

PROFESSIONAL EXAMINATIONS.

M.B., Ch.B.—There are four examinations for this degree. They must be passed in proper order, and before admission to them the candidate must be duly certified as having attended in the subjects involved. The First M.B. is divided into Part 1, chemistry and physics; Part 2, biology—(*a*) botany, (*b*) zoology. The parts may be taken separately or together. At the Second M.B. the candidate is examined in anatomy (including histology) and physiology; at the third in pathology, bacteriology, and pharmacology (including materia medica and practical pharmacy). The Final Examination, under new regulations, is divided into two parts, which may be taken separately. Part I consists of (*a*) forensic medicine and toxicology, and (*b*) hygiene and preventive medicine. Part II consists of (*a*) medicine, including dermatology, diseases of children, and mental diseases; (*b*) surgery, surgical pathology, and diseases of the eye and of the ear, nose, and throat; (*c*) obstetrics and gynaecology.

M.D.—A candidate for this degree must be a Bachelor of Medicine of at least one year's standing. He has a choice between presenting an original dissertation or undergoing a written (as well as practical and clinical) examination in medicine, and a written and practical examination in pathology, and one other subject selected by himself.

Ch.M.—A candidate must have held, since becoming Ch.B., and for not less than twelve months, a post in a public institution affording opportunity for the study of the branch of surgery in which examination is desired. The examination in Branch I comprises the general field of surgery; Branch II, obstetrics and gynaecology; Branch III, ophthalmology; Branch IV, otology, laryngology, and rhinology.

B.Sc. and M.Sc.—The ordinary degree of B.Sc. in the Schools of Anatomy and Physiology may be obtained by students in medicine who in their third year of study for the degree of M.B., Ch.B. complete the additional courses in these subjects prescribed for this degree. Candidates for the Honours degree of B.Sc. in anatomy or physiology who are students in medicine are required to attend courses in advanced anatomy and physiology for four terms after passing the Second Examination for the degrees of M.B., Ch.B. Graduates in science of this university, of not less than one year's standing from the date of their graduation as Bachelors, may proceed to the degree of M.Sc. by the presentation of an approved thesis on some subject coming within the scope of the Faculty of Science.

FEES.

The following examination fees are payable: Matriculation, £2; on readmission, £2. Each M.B. examination, £8 8s.; on readmission, £3 3s. M.D., including the conferring of the degree, £15 15s. Ch.M., £10 for the examination and £10 10s. for conferment of degree. Application for further information should be addressed to the Dean of the Medical School.

UNIVERSITY OF SHEFFIELD.

THE degrees of this university (M.B., Ch.B., M.D. and Ch.M., B.D.S., and M.D.S.), and the diploma of licentiate in dental surgery, are open to candidates of either sex. Candidates for a degree must have matriculated in the university or have passed such other examination as may be recognized for this purpose, and have passed the further examination in chemistry and physics.

PROFESSIONAL EXAMINATIONS.

A candidate for the degrees of M.B., Ch.B. must produce certificates that he will have attained the age of 22 years by the day of graduation; that he has pursued the courses of study required by the university regulations during not less than five years subsequent to the date of his matriculation or exemption from matriculation, and the passing of the further examination in chemistry and physics, three of such years at least having been passed in the university, one at least being subsequent to the passing of the First Examination. The following examinations must be passed in due order.

First Examination.—The subjects are chemistry, physics, and biology. Candidates who have passed the Intermediate Examination of the Faculty of Pure Science in any or all of the subjects of the First M.B. Examination will, on payment of the fee for the latter examination, be deemed to have passed it when they have passed in such subjects as they did not take for the Intermediate B.Sc. Examination. Candidates on presenting themselves for this examination are required to furnish certificates of having attended for not less than one year approved courses of instruction, after matriculation, and the passing of the further examination

in physics and chemistry, in (1) chemistry, inorganic and organic; (ii) physics; (iii) biology.

Second Examination.—The subjects are anatomy and physiology. The candidate must have completed the second year of professional study, must have passed the First Examination, and must have attended (1) courses on anatomy, including lectures and practical anatomy, during one year; (2) courses on physiology, including lectures and practical physiology, during one year.

Third Examination.—The subjects are pathology and pharmacology, anatomy, and physiology. Candidates must have completed the Lent term of the fourth year of medical study and the requisite courses in these subjects, including post-mortem clerkship for three months.

Final Examination.—The subjects are: Part I, forensic medicine and public health; Part II, medicine (including mental diseases and diseases of children), surgery, obstetrics (including gynaecology). Candidates for Part I must have completed Michaelmas term of the fifth year of study; candidates for Part II must have completed the fifth year of study.

M.D.—Candidates for the degree of Doctor of Medicine must have passed the examination for the degrees of M.B., Ch.B. at least one year previously, must present a thesis embodying observations in some subject approved by the Professor of Medicine, and must pass an examination in the principles and practice of medicine.

Ch.M.—Candidates for the degree of Master of Surgery must have passed the examination for the degrees of M.B., Ch.B. at least one year previously, and must, since taking the degrees of M.B., Ch.B., have held for not less than six months a surgical appointment in a public hospital or other public institution affording full opportunity for the study of practical surgery. The subjects of examination are systematic, clinical, and operative surgery, surgical anatomy, surgical pathology, and bacteriology.

Other information concerning this university will be found in the section devoted to Provincial Medical Schools.

UNIVERSITY OF WALES.

THE Charter and statutes of the University of Wales provide *inter alia* for a Faculty of Medicine and for the granting of the following degrees: Bachelor in Medicine (M.B.), Bachelor in Surgery (B.Ch.), Master in Surgery (M.Ch.), and Doctor in Medicine (M.D.).

A candidate for the M.B., B.Ch. is required to pursue a course of study of not less than six academic years subsequent to matriculation in the university, and of these years at least three must have been passed in one of the constituent colleges of the university. These are the University College of Wales, Aberystwyth; University College of North Wales, Bangor; University College of South Wales and Monmouthshire, Cardiff; and University College of Swansea. He must also hold an arts or science degree of the University of Wales, or of some other university approved for this purpose. Certain of the courses of study pursued for a B.Sc. or a B.A. degree may be counted as courses required for the degrees in the Medical Faculty.

The courses for the M.B., B.Ch. are divided into two sections, of which the first includes the preliminary subjects —physics, chemistry, botany, zoology; and the ancillary subjects—organic chemistry, human anatomy, and physiology. Study of the preliminary subjects and of organic chemistry must extend over at least one academic year; study of physiology and anatomy must extend over at least two academic years; the first section of the course must occupy not less than three years. The second section includes courses in pathology, bacteriology, pharmacology, hygiene and forensic medicine, medicine, surgery, and obstetrics and gynaecology, and cannot be commenced, except in the case of pharmacology, until the examinations relating to the preliminary and ancillary courses have been passed. Examinations in all the subjects are held in June of each year, and in medicine, surgery, obstetrics, and gynaecology in December also.

The university also offers courses of study in public health and in tuberculosis. Candidates for the diploma in public health (D.P.H.) and for the tuberculous diseases diploma (T.D.D.) must possess a medical qualification registrable for practice in Great Britain and Ireland, and must have completed courses of study as prescribed by the regulations either at the Welsh National School of Medicine, Cardiff, or at another institution approved by the university.

WELSH NATIONAL SCHOOL OF MEDICINE.

Students can complete the whole of their curriculum in the Welsh National School of Medicine, which is an integral part of the University College of South Wales and Monmouthshire, and qualify for the degrees of M.B., Ch.B. in the university.

Further information may be obtained from the Registrar, the University Registry, Cathays Park, Cardiff.

English Medical Corporations.

THERE are in England three medical corporations which grant licences to practise—the Royal College of Physicians of London, the Royal College of Surgeons of England, and the Society of Apothecaries of London. The first two combine for certain purposes to form what is known as the Conjoint Board in England. Details concerning this body, its component Colleges, and the third licensing body here follow.

THE CONJOINT BOARD.

THIS body—the Examining Board in England—deals with the qualifications of all candidates for the Licence of the Royal College of Physicians of London and for the Membership of the Royal College of Surgeons of England. It prescribes for them certain periods of study, and recommends those who pass the required examinations for the Licence and for the diploma of Member respectively. The successful candidate is then entitled to register as L.R.C.P.Lond., M.R.C.S.Eng. It performs the same task in connexion [illegible] blic health, tropical diseases, ophthalmic [illegible] y, psychological medicine, and laryngology and otology—jointly issued by the two Colleges in question. Under the present regulations every candidate for the L.R.C.P. and M.R.C.S. must (1) complete five years of professional study after passing a recognized preliminary examination and a recognized pre-medical examination in chemistry and physics; (2) comply with the regulations, which may be had from the Secretary, Examination Hall, Queen Square, London, W.C.1; and (3) pass the two professional examinations of which particulars appear below. The old regulations for the Conjoint diploma, of which an account was given in the Educational Number of the *British Medical Journal* for 1922, still apply to students who passed their preliminary examination in general education before January 1st, 1923.

PRESENT REGULATIONS FOR THE CONJOINT DIPLOMA.

The following is an outline of the present regulations for the L.R.C.P.Lond. and M.R.C.S.Eng. The full regulations and synopses and forms of certificate may be obtained from the Secretary.

PRE-MEDICAL EXAMINATION.

Students are required to pass a pre-medical examination in [illegible] ducted by the Conjoint Examining Board [illegible] years' curriculum of professional study [illegible] recognized by the Board—namely, the examination in chemistry and physics for the degree in Medicine of any university recognized by the Board, the higher school certificates of Oxford and Cambridge Universities and the Oxford and Cambridge Schools Examination Board, the higher certificates of London, Bristol, Durham [illegible] Matriculation Board of the Northern [illegible] Welsh Board higher certificate or the [illegible] in chemistry and physics conducted by [illegible] bodies whose degrees or diplomas are registrable on the *Medical Register*.

A candidate must enter for chemistry and physics together, and he will not be allowed to pass in one without obtaining at the same time at least half the number of marks required to pass in the other subject. He will be admitted to the examination on producing evidence of having passed the required preliminary education.

[illegible] partly written, partly oral, and partly [illegible] rejected in one or both subjects of the [illegible] admitted to re-examination until after the lapse of a period of not less than three months.

Professional Examinations.

There are two professional examinations, called the First and Final Examinations. The courses of study for the First Examination may be commenced before the pre-medical examination in chemistry and physics or some equivalent examination has been passed provided three terms of study of anatomy and physiology are completed after passing such examination.

First Professional Examination.—The subjects of this are: Section I, (*a*) Anatomy, including histology and embryology; (*b*) physiology, including biochemistry. Section II, Pharmacology, practical pharmacy, and materia medica. A candidate must have attended at a recognized Medical School courses of instruction in anatomy, including embryology, during five terms, in the course of which he must dissect the whole body, courses of instruction in physiology, including general biology, biochemistry, and biophysics during five terms, courses of instruction in pharmacology, practical pharmacy, and materia medica. A candidate may present himself for the two sections together or separately, but he must take parts (*a*) and (*b*) of Section I together until he has passed in one or both parts, but a candidate will not be allowed to pass in one part unless he obtains at the same time at least half the number of marks required to pass in the other part. Section II of the examination may be passed at any time before the candidate enters for the Final Professional Examination. A candidate who produces satisfactory evidence of having passed an examination in the subjects of Section I or of either part of Section I and of Section II in the examination for the degree in Medicine conducted at a university recognized by the Board will be exempted from further examination in such subject or subjects.

Final Professional Examination.—The subjects of this are: Section I, Pathology (including morbid anatomy, morbid histology, and clinical pathology) and bacteriology. Section II, Part I, Medicine, including medical anatomy, forensic medicine, and public health; Part II, Surgery, including surgical anatomy and the use of surgical appliances; Part III, Midwifery and gynaecology. The examination is partly written, partly practical, partly clinical, and partly oral. A candidate may take Sections I and II and the three parts of Section II of the Final Examination separately, or may take the whole examination together. He will be required to produce the certificates prescribed by the regulations before being admitted to the respective parts of the examination. A candidate who produces evidence of having passed an examination for a degree in Medicine in the subjects of pathology and bacteriology at a university recognized by the Board is exempted from Section I.

Fees.

The fee for the *Pre-Medical Examination* is three guineas, for re-examination in Chemistry two guineas, and for re-examination in Physics one guinea. The fee for the *First Professional Examination* is ten guineas, for re-examination after rejection in Section I six guineas, for re-examination after rejection in either part of Section I three guineas, for re-examination after rejection in Section II three guineas. The fee for admission to Section I of the *Final Professional Examination* is four guineas, for admission to Section II, Part I, ten guineas, Part II ten guineas, Part III six guineas; and the re-examination fees are respectively three guineas, six guineas, and four guineas.

ROYAL COLLEGE OF PHYSICIANS OF LONDON.

This College has three grades—its Licentiates, its Members, and its Fellows. The Licence is now only issued through the Conjoint Board. The Membership is only granted to those who have obtained the Licence, or to those who are registered practitioners and graduates of a recognized university; in any case they must be persons over 23 years of age. Candidates are examined in pathology and the practice of physic, partly in writing and partly viva voce; they are also examined in Latin, Greek, French, and German. The languages are not compulsory, but credit is given to those who show a knowledge of them. The fee for the Membership is £42, or in the case of a Licentiate £21. There is a fee of £10 10s., payable before entrance to the examination, which in the case of successful candidates is reckoned as part of the Membership fee. The body of Fellows is maintained by election from among the Members.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.

This College has two grades—Members and Fellows. The Members are admitted as stated in the section dealing with the Conjoint Board. The Fellowship is granted after examination to persons at least 25 years of age who have been engaged in professional studies for six years. There are two examinations for the Fellowship—the first in anatomy and physiology, which may be passed after the third winter session; the second, chiefly directed to surgery, which may be passed after six years of professional study. Candidates must pass the Final Examination of the Examining Board in England and be admitted Members of the College before admission to the Second Examination for the Fellowship, except in the case of graduates in medicine and surgery of not less than four years' standing of universities recognized by the College for the purpose, who are required to attend for one year the surgical practice of a general hospital recognized by the College after obtaining their degrees, which must be registrable in this country.

Fees.—At First Examination, £8 8s.; for re-examination, £5 5s. At Second Examination, £12 12s. Admission fee £10 10s. for members, £31 10s. for non-members.

SOCIETY OF APOTHECARIES OF LONDON.

This body confers a registrable diploma in medicine, surgery, and midwifery, now known as the L.M.S.S.A. (Licentiate in Medicine and Surgery of the Society of Apothecaries), on those successful at the following examinations:

Pre-medical Examination.—Chemistry and chemical physics.

Primary Examination.—This includes anatomy, physiology, and histology, and materia medica and pharmacy. Candidates will be excused any or all the subjects of the Primary Examination on producing evidence that they have passed equivalent examinations before an examining body recognized by the Society. Candidates referred in anatomy will be required to produce evidence of further work in the dissecting room before being admitted to re-examination.

Final Examination.—This is divided into three parts. Part I includes clinical surgery, the principles and practice of surgery, surgical pathology, operative manipulation, surgical anatomy, instruments and appliances. Part II includes clinical medicine; (*a*) the principles and practice of medicine (including therapeutics, pharmacy, and prescriptions), pathology, and morbid histology; (*b*) forensic medicine, hygiene, theory and practice of vaccination, and mental diseases. Part III includes midwifery, gynaecology, and diseases of newborn children, obstetric instruments and appliances.

The fee for the Primary Examination is £5 5s.; for the Final, £15 15s. The regulations and synopses relating to the several examinations, and other information, may be obtained from the Secretary, Court of Examiners, Apothecaries' Hall, Blackfriars, E.C.4.

Mastery of Midwifery.

The Society has recently instituted a Mastery of Midwifery, and issues a diploma under this title denoting the possession of specialized knowledge of ante-natal care, midwifery, and child welfare. The examinations take place in May and November, and candidates are required to submit certificates, etc., fourteen days before date of examination. It is intended to impose a severe test so as to ensure a high standard of professional knowledge, but the diploma will not be registrable under the Medical Acts. Admission is open to all who have been for not less than a year in possession of a registrable medical qualification, and who have had certain prescribed experience at recognized institutions concerned with obstetrics, ante-natal work, and child welfare work. Special conditions apply, until 1932, to practitioners of ten years' standing. The entrance fee for the examination is £10 10s., and a further fee of £10 10s. is payable by successful candidates before admission to the Mastery. Copies of the regulations may be obtained from the secretary at the address given in the preceding paragraph.

The Scottish Universities.

There are in Scotland four universities, each possessing a Faculty of Medicine, and having the right to confer degrees which admit the holder to the *Medical Register*. In essential points the regulations in their medical faculties for undergraduates are much alike, so that a general account can be given of all of them together.

The universities are those of Edinburgh, Glasgow, Aberdeen, and St. Andrews. The provision each of the cities in which these universities are situated makes for the education of medical students will be found in the section on Medical Schools in Scotland; here it need merely be said that degrees in medicine from Scotland as a whole have always enjoyed a high repute.

The degrees granted in medicine and surgery to candidates of either sex are four in number—Bachelor of Medicine (M.B.), Bachelor of Surgery (Ch.B.), Doctor of Medicine (M.D.), Master of Surgery (Ch.M.). The two former are not obtainable one apart from the other. Besides these degrees a diploma in tropical medicine and hygiene is obtainable from the University of Edinburgh, as also diplomas in psychiatry, public health, and radiology. As for public health, registrable degrees in this subject are granted by the University of Glasgow, while diplomas in public health may be obtained from the universities of St. Andrews and Aberdeen.

The conditions for admission of graduating students of medicine are the same as those in the Faculties of Arts or Science (for degrees in pure science). Prospective medical students are also required to pass a pre-registration examination in chemistry and physics.

Professional Education.

The regulations comply in all respects with the requirements and recommendations of the General Medical Council, and, in addition, necessitate definite study for stated periods of diseases of children, of the larynx, ear, and nose, of the skin, of ophthalmology, and of mental diseases. In respect of the various courses certificates must be obtained showing that the student has not only attended regularly, but has duly performed the work of the class. Out of the necessary five years of medical study, not less than two must be spent at the university whose degrees the student hopes to obtain, and the balance at any place officially recognized for such purpose. In each academic year there are two sessions—one lasting from the beginning of October to the middle of March, and the other from the middle of April to the beginning of July.

Professional Examinations.

The distinctive feature of the Scottish curriculum is that though nominally there are only four examinations, each of these may be, and habitually is, split up by the student into sections. Hence, a student may complete some stage of his career during the course of nearly every session. Thus, by the end of the first winter session the student may pass in zoology and chemistry. At the end of the first summer session he can finish with botany and physics, and with anatomy and physiology at the end of the second. Pathology and materia medica he will pass at the end of the third year, and so on, until the final examination in midwifery, surgery, and medicine, and the corresponding clinical subjects, at the end of the fifth year of study. At each examination the candidate may pass "with distinction," and a record is kept of the merit displayed, so that when the time comes for the candidate to graduate, one who has done well throughout can be declared as graduating with honours. A further point in the system is that the student's own teachers commonly take some part in his examination.

Of the four examinations, the first deals with physics, botany, zoology, and chemistry; the second with anatomy and physiology; the third with materia medica and pathology; the fourth with medicine and surgery (clinical and systematic), midwifery, clinical midwifery, and clinical gynaecology, and forensic medicine and public health. The first three examinations are held three times a year; the final twice a year.

Exemption from the first professional examination can be obtained by candidates who have passed an arts, science, or medical degree examination in its subjects at any recognized university. When a candidate presents himself for an examination in several of its parts, but is not successful in all of them, he is credited at the next examination with those subjects in which he has already been approved.

The Higher Degrees.

It is open to those who are already M.B., Ch.B. to proceed either to the M.D. or the Ch.M. A candidate for the former must have been engaged for not less than one year in work in the medical wards of a hospital, or in scientific research in a recognized laboratory, or in the Naval or Military Medical Service, or have been at least two years in general practice, and he must be 24 years of age. He has to write a thesis on any subject not exclusively surgical, and is examined in clinical medicine and in some one or other of its special departments. The regulations for candidates for the Ch.M. are of a corresponding character, a period of surgical work in a hospital or elsewhere being substituted for medical work, and the thesis being on a surgical rather than a medical subject. He is examined in surgical anatomy, clinical surgery, operative surgery, and in some of the special departments of surgery.

Fees.

It is estimated that the class, examination, and other fees for the M.B., Ch.B. come altogether to about £256, the separate examination fees included in this calculation being as follows:

	£	s.	d.
First Professional	9	9	0
Second Professional...	7	7	0
Third Professional	6	6	0
Final	11	11	0

Re-entry in any subject in which the candidate has failed entails a fresh payment of £1 1s. Candidates for the M.D. and Ch.M. pay £21, and on re-entry £5 5s.

More detailed information with regard to the University of Edinburgh can be obtained from the *Medical Programme*, price 6d., which is published by Mr. Thin, 55, South Bridge, Edinburgh, or on application to the Dean of the Faculty of Medicine. Similar information about Glasgow should be sought from the Assistant Clerk, Matriculation Office, Glasgow. With regard to Aberdeen, application may be made to the Secretary of the Medical Faculty, Marischal College. In respect of St. Andrews information can be obtained either from the Secretary of the University, or, alternatively, the Secretary of the United College, St. Andrews, or the Secretary of University College, Dundee, these being the two constituent colleges of the University of St. Andrews.

Finally, it should be mentioned that in connexion with all the Scottish universities there are valuable bursaries and scholarships, some information as to which will be found in the article on Medical Schools.

The Carnegie Trust.

The following is a summary of the regulations made by the Carnegie Trust for the Universities of Scotland for assistance in the payment of class fees in the universities and extra-mural colleges of Scotland.

Applicants must be over 17 years of age; they must be of Scottish birth or extraction, or have attended for two years, after the age of 14, at a school or institution under inspection of the Scottish Education [illegible]nts so qualified who have been pupils of sch[illegible]h Education Department will be eligible for [illegible]ent of class fees if they have obtained the [illegible]he Department, provided that it bears evide[illegible] education as is required by the universities [illegible] curricula, or that it has been supplemented [illegible] in the Scottish Universities Preliminary or other examination as will satisfy the above requirement of the universities. Where applicants have not been pupils of schools under the Scottish Education Department, or where other good ground for not having obtained the leaving certificate can be shown, the Executive Committee has power to accept instead what it deems equivalent evidence of attainments.

Applicants in the Faculties of Arts and Science must have had their course of study for each academic year approved by the University Adviser of Studies, and they must have passed the graduation examinations belonging to the previous stage of their curriculum before becoming eligible for assistance in the payment of fees of classes belonging to a further stage. Beneficiaries must submit to the Executive Committee at the end of each session particulars as to their attendance and work, any distinctions gained, and any graduation examinations passed.

The annual allowance towards payment of class fees offered to beneficiaries by the Trust in the Faculty of Medicine is £19 for four years, in all £76. Any unexpended part of a grant will be carried forward to the succeeding year. In combinations of Faculties the allowances available for beneficiaries are: Arts and Medicine—two Arts grants of £8 and four Medicine grants of £19, in all £92; Science and Medicine—two Science grants of £17 and four Medicine grants of £19, in all £110.

Applicants, in writing for application forms, must name the university and faculty in which they intend to study, and state whether they have previously obtained the benefits of the Trust. Applications must be lodged not later than October 25th for the winter session, or May 10th for the summer session. Payments are made by means of fee coupons, and fees already paid are not refunded.

The Scottish Corporations.

THERE are three medical corporations in Scotland—the Royal College of Physicians of Edinburgh, the Royal College of Surgeons of Edinburgh, and the Royal Faculty of Physicians and Surgeons of Glasgow. Their licences can be *separately obtained only by persons who are already in* possession of a recognized qualification—in surgery in the case of the College of Physicians, and in medicine in the case of the College of Surgeons and the Faculty of Physicians and Surgeons of Glasgow. All others must submit to the examinations held by the Conjoint Board, which the three corporations have combined to form. Details concerning this Board and its component colleges follow. The conditions on which their higher qualifications are granted will be found set forth separately in connexion with each corporation.

THE CONJOINT BOARD IN SCOTLAND.

THIS body has charge of all questions connected with candidates for the Conjoint Licences of the Royal College of Physicians of Edinburgh, the Royal College of Surgeons of Edinburgh, and the Royal Faculty of Physicians and Surgeons of Glasgow. Those finally approved by it are entitled to registration and to the initials denoting the Licences of the three bodies concerned—namely, L.R.C.P.Ed., L.R.C.S.Ed. and L.R.F.P.S.Glas. The Board requires all candidates to comply with the regulations of the General Medical Council. It has an arts examination of its own, but is prepared to accept in its place any of the other educational tests approved by the General Medical Council. All candidates must obtain registration with the General Medical Council.

Professional Curriculum for Candidates registered as Medical Students after January 1st, 1923.

Subsequent to registration as a medical student, the candidate must pass not less than five years in medical study, each comprising a winter and a summer session. The Board does not insist that candidates shall pursue their study at any particular place, and is prepared to accept certificates of having attended the necessary courses from any recognized medical school.

Its examinations are four in number, each of them being held four times every year, and these will fall to be held three times in Edinburgh and once in Glasgow during the next period: it is open to candidates to present themselves for examination at either place. The first examination deals with general biology, systematic and practical; the second with anatomy, embryology, physiology, biochemistry and biophysics; the third with pathology (including bacteriology and morbid anatomy) and pharmacology, theoretical and practical; and the final with (1) medicine, including therapeutics, applied anatomy and physiology, and clinical pathology, with practical medicine; (2) surgery, including applied anatomy and physiology, clinical pathology, and practical surgery; (3) midwifery and diseases of women, clinical obstetrics and gynaecology, with practical midwifery; and (4) medical jurisprudence and public health. All candidates for the Final Examination must complete portions (1) (2) and (3), which must be taken together, within a period of nineteen months.

These examinations must be passed in due order, and before admission to any of them the candidate must supply certificates showing that he has completed the due periods of study of their subjects. He can present himself in any single subject of the first three examinations. As regards the Final Examination, a candidate can present himself in medical jurisprudence and hygiene at any time after completion of the third examination and of his study of these subjects: but in medicine, surgery, and midwifery he cannot present himself until the completion of five years' study, and he must take them all simultaneously. A candidate who takes up several subjects of an examination or the whole of the subjects at one time, but fails in some of them, is credited at the next examination with those subjects in which he has been approved.

Part or entire exemption from the first three examinations may be granted to those who have already passed before other bodies examinations deemed by the Board equivalent to its own, but all candidates for the Conjoint Licence must sit for the Final Examination, and at no examination can a candidate present himself within three months of his rejection by some other licensing body.

FEES.

It is estimated that the total cost of lectures and fees for the Conjoint Licence is about £170. The separate examination fees are as follows: First, Second, and Third Professional, £5 each; Final £15. On re-entry for any of the first three examinations £3, and on re-entry for the Final, £5. If the re-entry is only in one or two subjects of the First, Second, or Third Examination the fees are smaller.

Information concerning this Board should be sought either from Mr. David Thomson, 49, George Square, Edinburgh, or from Mr. Walter Hurst, Faculty Hall, 242, St. Vincent Street, Glasgow.

ROYAL COLLEGE OF PHYSICIANS OF EDINBURGH.

THIS College has three grades—Licentiateship, Membership, and Fellowship—all of which are open to men and women. The regulations applying to candidates for the Licentiateship have already been generally indicated. If desirous of receiving it apart from those of the other two corporations they must be duly registered medical practitioners. Candidates will be required to pass an examination corresponding to the medical part of the Final Examination of the Conjoint Board, and conditioned in the same way, and also an examination in materia medica. The fee for examination is 15 guineas, a special examination being obtainable on due cause being shown, and on payment of 5 guineas extra. Ordinary examinations take *place monthly on the first Wednesday and Thursday, except* in September and October.

Candidates for the Membership must be either Licentiates of a British or Irish College of Physicians, or alternatively graduates of medicine of a university, approved by the Council, and in either case not less than 24 years of age. Candidates are examined in medicine and therapeutics, also on one or more departments of medicine specially professed, and approved by the Council, in which a high standard of proficiency will be expected. The fee to be paid by a candidate for the Membership is £36 15s. The examination is held quarterly, and application for admission to it must be made a month previous to its date.

For the Fellowship the candidate must have been a Member of the College for at least three years, and, if accepted, pay *fees, including £25 stamp duty, amounting* altogether to £64 18s. Further details can be obtained on application to the Secretary of the College.

ROYAL COLLEGE OF SURGEONS OF EDINBURGH.

THIS College has two grades—its Licence and its Fellowship. Licentiates may be of either sex, and for the Fellowship women are eligible also.

Licence.

As an original qualification the Licence is only granted after fulfilment of the regulations of the Scottish Conjoint Board, but as an additional qualification it can be obtained by those already possessed of a registrable or equivalent qualification in medicine. In this case the candidate has to pass a written, oral, and clinical examination in surgery and surgical anatomy, and may be asked to operate on the dead body.

The fee is £15 15s., of which £10 10s. is returned to unsuccessful candidates. On due cause being shown, a special examination may be granted, the fee being £20, of which £10 is returned to a candidate if he is not approved.

Fellowship.

Candidates for the Fellowship must be not less than 25 years of age, and have been in the practice or study of their profession subsequent to registration for at least two years, and must hold either a surgical degree from a university recognized for that purpose by the College, or a registrable diploma obtained as the result of an examination which includes surgery as well as medicine and midwifery. Candidates are examined in (*a*) the principles and practice of surgery, including surgical anatomy, (*b*) clinical surgery, and (*c*) one optional subject, which they may choose from among the following: surgical pathology and operative surgery, ophthalmology, laryngology, otology and rhinology, gynaecology, obstetric surgery, anatomy, and dental surgery and pathology. The examination is written, oral, and clinical or practical. A candidate who desires to be examined must give one month's notice. After having passed the examination he must lodge with the Clerk to the College a petition asking that his name be placed before the College for election as a Fellow. This petition must be signed by two Fellows, as proposer and seconder, who should be sufficiently acquainted with the candidate to vouch that he is in every way a suitable candidate for the Fellowship. It is desirable that either the proposer or the seconder should be resident in Edinburgh. *Candidates are not allowed to appear more than three times at the examinations.*

Licentiates of the college pay £40, and others £50. For further information application should be made to the Clerk of the College, Mr. David Thomson, 49, George Square, Edinburgh, from whom a copy of the *Laws Relating to the Fellowship by Examination* may be obtained.

ROYAL FACULTY OF PHYSICIANS AND SURGEONS OF GLASGOW.

This body possesses two classes—Licentiates and Fellows. The regulations applying to the former correspond with those respecting candidates for the Licence of the Royal College of Surgeons of Edinburgh. Candidates for the single Licence are examined in surgery (including clinical surgery and surgical anatomy). The fee is £15 15s. and examinations are held quarterly. Candidates for the Fellowship must be qualified medical men of not less than two years' standing and 24 years of age. Candidates approved at this examination are then eligible for election as Fellows. The Faculty can also elect four Fellows annually without previously submitting them to examination, provided they "have highly distinguished themselves in medical science or practice." They must be of not less than ten years' standing and 40 years of age.

The fee for the Fellowship is £50. Further information can be obtained from Mr. Walter Hurst, Faculty Hall, 242, St. Vincent Street, Glasgow.

Irish Universities and Corporations.

MEDICAL REGISTRATION IN THE IRISH FREE STATE.

The Medical Practitioners Act, 1927 (Irish Free State), provides for the establishment of a Medical Registration Council for the Irish Free State. The main functions of the Council will be (1) to keep a register of medical practitioners who may desire to practise permanently or temporarily in the Irish Free State, and (2) to exercise disciplinary power with regard to all medical practitioners who are on the register and engaged in practice in the Irish Free State. The first schedule of the Act contains the agreement between Great Britain, the Irish Free State, and Northern Ireland. This agreement provides for the nomination of a member of the General Medical Council, formerly made for Ireland by His Majesty on the advice of the Privy Council, to be made henceforth by His Majesty in Council on the recommendation of the Governor of Northern Ireland. The nominations of members of the General Medical Council by universities and medical corporations in Ireland and the election of a member of the General Medical Council by registered medical practitioners in Ireland will be in all respects the same as heretofore. The constitution of the General Medical Council and of the several Branch Councils as formerly existing under the Medical Acts, and the powers of holding qualifying examinations and granting diplomas for the purpose of registration in the general *Register* formerly vested in certain universities and medical corporations in Ireland, are not affected by the establishment of the Irish Free State or of Northern Ireland, and for the purpose of the preparation and keeping of the general *Register* the General Medical Council and the Branch Council for Ireland shall have the same powers and jurisdictions under the Medical Acts as they exercised formerly. The agreement provides also that any person who is or shall be registered in the general *Register* shall be entitled on the payment of a prescribed fee to be registered in the *Irish Free State Register*, but this fee will not be payable by any person who, on the date of the establishment of the *Irish Free State Medical Register*, is registered on the general *Register*. Then follow provisions with regard to the erasure from the *Register* of the name of a person on account of misconduct.

The *Irish Free State Medical Register* was established on May 26th, 1928, this being the date appointed by the Medical Registration Council. The *Register* on establishment contained the names of every medical practitioner who was registered in the general *Medical Register* immediately before May 26th, 1928, and who either was then resident in the Free State, according to his address as stated in the general *Register*, or was living outside the Free State and applied to the Council within one month before May 26th, 1928, to be registered. No fee for registration was charged in such cases.

For registration in the *Irish Free State Register* subsequent to its establishment a fee is required, together with a prescribed form of application. A person is eligible for registration if he is at the time of application registered in the general *Medical Register*, or if he possesses the requisite qualifying diploma granted by colleges or bodies in the Free State as set out in the Act. Application for further information may be made to the Registrar, Medical Registration Council, Room 123, Custom House, Dublin.

THE IRISH UNIVERSITIES.

There are three universities in Ireland, each with a medical faculty. These are, in the Irish Free State, the University of Dublin (usually known as Trinity College, Dublin), and the National University of Ireland; and, in Northern Ireland, the Queen's University of Belfast.

UNIVERSITY OF DUBLIN: TRINITY COLLEGE.

This university grants two degrees in medicine (M.B. and M.D.), two in surgery (B.Ch. and M.Ch.), two in midwifery (B.A.O. and M.A.O.), and a post-graduate diploma in public health. It also grants post-graduate diplomas in gynaecology and obstetrics, for which nine months' study is required, and in psychological medicine, for which twelve months' study is required. The degrees are granted to those who, having passed the professional examination, have also graduated in arts.

Professional Examinations.

A candidate for the Final Examination for the M.B., B.Ch., and B.A.O. degrees must be a matriculated student of at least five years' standing. The examinations which students must pass are the Preliminary Scientific, the Intermediate Medical, and the Final. Before admission to any of these examinations students must have completed the courses of study in the subjects involved.

Preliminary Scientific.—This covers (*a*) chemistry, (*b*) physics, (*c*) botany and zoology; the three divisions may be taken together or at different times.

Intermediate Medical.—This is divided into two parts: (*a*) anatomy, physiology, organic chemistry, and histology; (*b*) applied anatomy and applied physiology. The two parts may be taken separately or together.

Final Examination.—Part I: Hygiene and medical jurisprudence, pathology and bacteriology, materia medica and

therapeutics. Part II: (*a*) Midwifery and gynaecology; (*b*) medicine and mental diseases; (*c*) surgery in all branches, including clinical ophthalmology. The three sections of Part II may be taken separately or together. In either case the full curriculum must have been completed, and the Final Examination cannot be completed before the end of the fifth year.

M.D.—The candidate must have passed all the qualifying examinations in medicine, surgery, and midwifery, and have taken, or have been qualified to take, the degree of B.A. three years previously. He must send in a thesis for approval. Subsequently the Regius Professor of Physic and an assessor will discuss with him questions connected with the thesis, and also examine him viva voce on other medical subjects of a more general nature.

M.Ch.—The candidate must be a B.Ch. of not less than three years' standing and have been engaged in practice for two years.

M.A.O.—The candidate must be a B.A.O. of not less than two years' standing and must produce satisfactory evidence of having been engaged for two years in the study of obstetric science. The examination is specially directed to obstetrics and practical gynaecology.

Further information regarding courses of instruction, etc., may be obtained from the Registrar of the School of Physic, Trinity College, Dublin.

QUEEN'S UNIVERSITY, BELFAST.

THE degrees granted by the Medical Faculty of this university are as follows: Bachelor of Medicine (M.B.), Bachelor of Surgery (B.Ch.), Bachelor of Obstetrics (B.A.O.), Doctor of Medicine (M.D.), Master of Surgery (M.Ch.), Master of Obstetrics (M.A.O.). The university also confers a diploma in public health. The first three degrees mentioned serve as a qualification for admission to the *Medical Register*, and are not granted separately. In addition to matriculating and passing his professional examinations, a candidate for these degrees must have passed three of the regulation five years as a student at the Belfast School of Medicine. Degrees in dental surgery (B.D.S. and M.D.S.) are conferred by the university, and also a diploma in dental surgery (L.D.S.).

PROFESSIONAL EXAMINATIONS.

The examinations for the M.B., B.Ch., B.A.O. are four in number. The first deals with: (1) inorganic, organic, and practical chemistry, (2) experimental and practical physics, (3) botany and practical botany, (4) zoology and practical zoology. It is divided into two parts, of which botany and zoology form one. The Second Examination covers anatomy and physiology (both theoretical and practical), and may be taken at the end of the second year of the student's career. The Third Examination includes: (1) pathology and practical pathology, (2) materia medica, pharmacology, and therapeutics, (3) medical jurisprudence, and (4) hygiene. To be valid a certificate in regard to the study of the subjects of this examination must show that the work has been done after the Second Examination has been passed.

The Final Examination includes: (1) medicine, (2) surgery, (3) midwifery, (4) ophthalmology and otology. The student must pass in all subjects at once at the end of his fifth year, or he may divide the examination into two parts—namely, (1) systematic, (2) clinical, practical, and oral. The first part may be taken at the end of the fourth year, but for the second part the candidate may not present himself until the end of his fifth year, but students invariably take both parts at the end of their course. No certificate in regard to the study of the subjects of this examination will be valid unless the work was done subsequent to passing in all the subjects of the Second Examination.

THE HIGHER DEGREES.

Candidate for the degree of Doctor of Medicine must be graduates in medicine of at least three years' standing, unless they hold also a degree of the university in arts or science, in which case a standing of two academic years will suffice. Moreover, candidates must be able to show that the interval has been passed in the pursuit of such courses of study or practical work as may be prescribed. The degree may be conferred either (*a*) after a formal examination, or (*b*) in recognition of the merits of a thesis or of some piece of original study or research carried out by the candidate, followed by an oral or other examination in its subject. When an ordinary examination is imposed it will include (1) a written paper on the principles and practice of medicine, (2) a commentary on a selected clinical case, (3) a clinical and viva voce examination, and (4) a written paper and clinical or practical and viva voce examination on a subject chosen from the following list: (*a*) human anatomy, including embryology; (*b*) physiology, (*c*) pathology, (*d*) pharmacology and therapeutics, (*e*) sanitary science and public health, (*f*) forensic medicine and toxicology, (*g*) mental diseases. The regulations for the degrees of M.Ch. and M.A.O. are of the same general nature.

NATIONAL UNIVERSITY OF IRELAND.

THE National University of Ireland carries on most of its educational work through three constituent colleges—one in Dublin, one in Cork, and one in Galway. Each of these provides a full medical curriculum, and all candidates for the medical degrees of the university must pass three of their five years of study at one or other of them. These years do not count except after matriculation or recognition as a student of the Medical Faculty obtained in some other fashion. The candidates at each constituent college are examined by the university, and a common standard of education is secured by all courses of instruction and the regulations concerning them having to be approved by the Senate, after considering report thereon from the Board of Studies of the university. In addition to the ordinary degrees in medicine and surgery, the university grants those of Bachelor and Master of Obstetrics, Bachelor and Doctor of Science in Public Health, and Bachelor and Master in Dental Surgery, as well as Diplomas in Public Health, in Mental Diseases, and in Tropical Medicine and Hygiene.

Application for other information may be made to the Registrar, National University of Ireland, 49, Merrion Square, Dublin, C.17.

THE IRISH CORPORATIONS.

THERE are, in the Irish Free State, three licensing bodies other than the Medical Faculties of the universities: and in Dublin, just as in London, there is a Royal College of Physicians of Ireland, a Royal College of Surgeons in Ireland, and an Apothecaries' Hall. In Dublin, as in London and in Edinburgh, the two Colleges have formed an examining Conjoint Board, which is responsible for the recommendation of candidates to the two bodies for their respective licences. The Apothecaries' Hall of Ireland, like the Apothecaries' Society of London, gives its licence separately.

THE CONJOINT BOARD IN IRELAND.

THIS body requires of candidates either the passage of its own preliminary examination in the subjects of general education or proof that the candidate has passed one of the tests accepted by the General Medical Council as well as passing in the pre-registration examinations in chemistry and physics and biology.

PROFESSIONAL EXAMINATIONS.

There are three professional examinations, the first of which cannot be passed earlier than the end of the second winter session, nor the final before the conclusion of full five years of medical study. Before being admitted to any of them the candidate must show that he has studied the different subjects in practice and theory for the requisite periods, certificates to this effect being accepted from the authorities of most of the recognized medical schools at home and abroad. The first examination deals with (*a*) anatomy, and (*b*) physiology and histology. The second examination deals with (*a*) pathology, (*b*) materia medica, pharmacy, and therapeutics and ophthalmology, and may be taken separately.

Final Examination.—This is divided into three divisions, which cannot be completed until at least five years have passed in medical studies other than those for the pre-registration examinations, and five years at least since the beginning of the curriculum. The divisions are: (*a*) medicine, including fevers, mental diseases, and diseases of children; (*b*) surgery, including operative surgery; (*c*) midwifery, including diseases of women and newborn children, and the theory and practice of vaccination.

Fees.—Preliminary Examination, £2 2s. Re-examination, £2 2s. Pre-Registration Examination, £3 3s. Re-examination in Chemistry, £2 2s.; in Physics, £1 1s. First Professional Examination, £26 5s.; Second, £15 15s.; Final, £6 6s. Re-examination fee is £2 2s. for each division.

Diploma in Psychological Medicine.

There are two examinations in connexion with this diploma: Part I consists of (*a*) anatomy and physiology of the nervous system, (*b*) psychology. Part II—(*a*) neurology, including clinical and pathological neurology; (*b*) psychological medicine, including its legal relationships.

Fees.—£6 6s. for each part.

Further information can be obtained from Mr. Alfred Miller, Secretary of the Committee of Management, Royal College of Surgeons, St. Stephen's Green, Dublin.

ROYAL COLLEGE OF PHYSICIANS OF IRELAND AND ROYAL COLLEGE OF SURGEONS IN IRELAND.

The Diploma in Public Health.

Every candidate for the Diploma in Public Health must observe the following rules:

Rule 1. A period of not less than two years shall elapse between the attainment by a candidate of a registrable qualification in Medicine, Surgery, and Midwifery and his admission to the Final Examination for a Diploma in Public Health.

Rule 2. The curriculum for the Diploma in Public Health shall extend over a period of not less than twelve calendar months subsequent to the attainment of a registrable qualification.

Rule 3. Every candidate shall produce evidence of having attended, during a period of not less than five months, at an institution approved by the Licensing Body granting the Diploma, practical instruction in—

(*a*) Bacteriology and Parasitology (including Medical Entomology), especially in their relation to diseases of man, and to those diseases of the lower animals which are transmissible to man;
(*b*) Chemistry and Physics in relation to Public Health;
(*c*) Meteorology and Climatology in relation to Public Health.

At least 180 hours must be devoted to Course (*a*), of which not less than 150 hours shall be work.
At least 90 hours must be of which not less than 70 hours shall be work.
At least 10 hours must

Rule 4. Every candidate shall produce evidence of having received, during not less than 80 hours, at an institution or from teachers approved by the Licensing Body granting the Diploma, instruction in the following subjects:

(*a*) The Principles of Public Health and Sanitation (30);
(*b*) Epidemiology and Vital Statistics (20);
(*c*) Sanitary Law and Administration (including Public Medical Services) (20);
(*d*) Sanitary Construction and Planning (10).

[The numbers indicate the normal proportion of time to be given to each subject.]

Rule 5. Every candidate shall produce evidence that he has attended for three months on the clinical practice of a recognized Hospital for Infectious Diseases, and has received therein instruction in the methods of administration. At least thirty daily attendances of not less than two hours in each week shall be required.

Rule 6. Every candidate shall produce evidence that he has, during a period of not less than six months, been engaged in acquiring a practical knowledge of the duties, routine and special, of Public Health Administration under the supervision of a Medical Officer of Health, who shall certify that the candidate has received, from this Officer or other competent Medical Officer, during not less than three hours on each of sixty working days, practical instruction in these duties, and also those relating to:

(*a*) Maternity and Child Welfare Service;
(*b*) Health Service for Children of School Age;
(*c*) Venereal Diseases Service;
(*d*) Tuberculosis Service;
(*e*) Industrial Hygiene;
(*f*) Inspection and Control of Food, including meat and milk.

Certificates of having received the prescribed instruction in Public Health Administration must be given by a Medical Officer of Health who devotes his whole time to Public Health work; or by the Medical Officer of Health of a Sanitary Area having a population of not less than 50,000, or in Ireland the Medical Superintendent Officer of Health of a County or County Borough having a population of not less than 50,000.

Rule 7. The examination for the Diploma shall be divided into two parts, Part I and Part II.

Rule 8. The examination for Part I shall include the following subjects:

Bacteriology and Parasitology (including Medical Entomology);
Chemistry and Physics, and Meteorology and Climatology, in relation to Public Health.

Rule 9. The examination for Part II shall include the following subjects:

Hygiene and Sanitation (including Sanitary Construction);
Epidemiology and Infectious Diseases;
Sanitary Law and Vital Statistics;
Public Health Administration.

The examination shall be written and oral, and shall include practical examinations in Infectious Diseases; Food inspection; Inspection of Premises—dwellings, factories, workshops, schools, etc.

ROYAL COLLEGE OF PHYSICIANS OF IRELAND.

Those whose names already appear on the *Medical Register* can obtain the separate Licence in Medicine of this College and its Licence in Midwifery. In either case an examination has to be passed in the subjects indicated, questions on midwifery, hygiene, and jurisprudence being included in the examination for the Licence in Medicine. For the Licence in Midwifery practitioners of over five years' standing are exempted from examination by printed questions. The other grades of the College are Members and Fellows. The former are admitted after an examination which is open to all university graduates in medicine and Licentiates in medicine of the Royal College of Physicians, and deals with the general subjects of medicine. Fellows are selected, by vote, from among the Members of the College.

Fees.—For the Licence in Medicine, 15 guineas; Special Examination, £21. For the Licence in Midwifery, 8 guineas; Special Examination, 16 guineas. For the Membership, 20 guineas to a Licentiate of the College, 35 guineas to others; a special examination costs 10 guineas extra. The Fellowship, £35, in addition to stamp duty, £25.

Information as to special examinations and other matters can be obtained from the Registrar, the Royal College of Physicians, Kildare Street, Dublin.

ROYAL COLLEGE OF SURGEONS IN IRELAND.

This body, besides granting a Licence in Surgery, admits those possessed of registrable surgical qualifications to its Fellowship under certain conditions. Its Licence is usually granted conjointly with that of the College of Physicians, but it is given separately to holders of a registrable qualification in medicine, provided the College is satisfied that adequate courses of study have been pursued, and provided its own provisional examination is passed. This examination is held on its behalf by the Conjoint Board, and is identical with the ordinary surgical portion of the examinations imposed by that body.

The Fellowship.—Candidates for the Fellowship must pass two examinations, of which the first is in anatomy (including dissections), physiology, and histology; and the second in surgery (including surgical anatomy) and pathology. Both examinations are partly written, partly practical, and partly viva voce; while the final examination includes the performance of operations. All subjects of either examination must be passed at one time, and in neither can a candidate be admitted who has been rejected in any of its subjects by any other licensing body within three months. Candidates are not admitted to the Primary Examination except on evidence that they have already passed an examination in anatomy, physiology, and histology, held by some university or other body whose degrees or licences entitle the holder to admission to the *Medical Register*; if, however, the candidate's name is on the Colonial or Foreign List in the *Medical Register*, at the discretion of the Council. Candidates for the Final Examination must be over 25 years of age, produce a certificate of general good conduct signed by two or more Fellows of the College, and, if successful, must make a declaration before admission to the effect that they do not conduct dispensing practices, and will not do so as long as they are Fellows.

Fees.—Candidates for the Licence pay 5 guineas for examination, which sum, if they pass, is counted as part of the fee payable on admission to the Licence, this being 25 guineas. Candidates for the Fellowship pay 5 guineas for each examination, the total of 10 guineas being reckoned as part of the fee payable on admission to the Fellowship. That fee is 25 guineas in the case of those who are already Licentiates, and 40 guineas in the case of others.

APOTHECARIES' HALL OF IRELAND.

A DIPLOMA is granted by this Hall which entitles the holder to be registered as a practitioner of medicine, surgery, and midwifery, and confers also the privileges of an apothecary. Women candidates are eligible.

Fees.—Primary Examination (Parts I and II), £21; Final Examination, £21. Subjects of examination: Primary, Part I, Anatomy and Physiology. Primary, Part II, Materia Medica, including Pharmacy; Medical Jurisprudence and Hygiene; Pathology. Final Examination: Medicine, Surgery, and Midwifery. Candidates must

enter for and pass at the one time in Anatomy and Physiology. They are at liberty to enter for the subjects of the Final Examination at separate times, but the Final Examination cannot be completed until a period of three years has elapsed from the date of passing Primary Examination, Part II.

Application for other information should be made to the Registrar, 95, Merrion Square, Dublin.

MEDICAL SCHOOLS AND COLLEGES.

LONDON.

INFORMATION as to the fees at each of the various metropolitan medical schools, and the scholarships, prizes, and junior appointments which they offer, will be found in the following pages. The courses they provide are fundamentally the same, and in all of them the arrangements made are such as to meet the requirements of students of every class—of those who are aiming at the diplomas of the English Conjoint Board or the Apothecaries' Society, not less than of those who have London or other university degrees in view. At all, too, special facilities are offered to students who have commenced their professional education at Oxford or Cambridge, and are seeking the medical degrees of those universities.

CHARING CROSS HOSPITAL.

THIS school, with its hospital, is situated in the centre of London, and is easily accessible. Primary and intermediate students attend lectures and practical work at King's College. The final studies are taken in the school and hospital, where systematic lectures, demonstrations, and tutorial classes are arranged to cover all the subjects necessary for the qualifying examinations. Departments are also available for the other final subjects of bacteriology, clinical pathology, biochemistry, materia medica, public health, operative surgery, and for research work. An Institute of Pathology, with a whole-time staff of scientific workers and fully equipped laboratories, has been established in the school. Students receive their training in preventive medicine, pathology, and bacteriology here, and are encouraged to undertake research.

A number of scholarships and exhibitions are awarded to university and other students, particulars of which can be obtained from the Dean.

Fees.—The fees are as follows: Entrance, Primary and Intermediate, 10 guineas; Final, 8 guineas. Annual, 38 guineas.

Further information may be obtained on application to the Dean of the Medical School, Charing Cross Hospital, London, W.C.2.

GUY'S HOSPITAL.

THE hospital contains 646 beds in constant occupation. Twenty-five beds are set apart for diseases of the eye, and 42 for the most urgent and interesting medical cases, which form the subjects of the weekly clinical lectures. There are special wards of 49 beds for the reception of cases of diseases of women and for cases of difficult labour. Beds are also allotted to the throat and ear departments, the departments of orthopaedics, neurology, and dermatology, the department for the treatment of diseases of the genito-urinary system, and the children's department; there are also some special beds for the treatment of syphilis.

The residential college fronts the east gate of the hospital, providing accommodation for resident students. This contains a dining hall, reading rooms, a library of general literature, and a gymnasium for the use of the residents and of the members of the Clubs Union. The athletic ground at Honor Oak Park is reached from the hospital in fifteen minutes. The Gordon Museum of Pathology, the Wills Library, the departments of chemistry, physics, pathology, and pharmacology, and the school buildings in general, afford opportunities for a liberal education and for research, and provide the full curriculum for all medical degrees and diplomas. New departments of anatomy, physics, and biology have recently been completed. They are equipped on the most modern lines, and provide ample accommodation for teaching and research. Special classes are held for the First and Second examinations for medical degrees of the University of London, for the pre-medical examination, and for the First and Final F.R.C.S.Eng. Examinations. Special teaching is provided to meet the requirements of the Universities of London, Oxford, and Cambridge in general pathology and pharmacology.

Appointments.—All appointments are made according to the merits of the candidates, as determined by a committee of the medical staff. Sixteen out-patient officers, eight house-physicians, twenty assistant house-surgeons, eight house-surgeons, two ophthalmic house-surgeons, two genito-urinary house-surgeons, two house-physicians (children's department), two house-physicians (dermatological and neurological), and nine resident obstetric assistants are appointed annually. The house-physicians and house-surgeons, obstetric residents, ophthalmic house-surgeons, and genito-urinary house-surgeons hold office for six months each, and receive free board and lodging in the college. Every student is provided with rooms and commons in the hospital during the period of his "take in" as senior dresser. In addition to the clerkships and dresserships in the medical and surgical wards, students are appointed to the posts of clinical assistant dresser, or clerk in the special departments of ophthalmology, laryngology, gynaecology, diseases of children, diseases of the nervous system, dermatology, otology, actinotherapeutics, anaesthetics, dentistry, orthopaedics, vaccine, tuberculosis, fractures, and genito-urinary and venereal disease; clinical assistantships in the various special departments are open to post-graduates.

Scholarships, Prizes, etc.—The following scholarships in Arts and Science are awarded. A. Open Junior Scholarships: (1) An Arts Scholarship of the value of £100, (2) a Science Scholarship of the value of £100; these are awarded annually in June or July. (3) A War Memorial Scholarship of the value of £200, awarded alternately in Arts and Science. This scholarship is open every other year; the next award will be made in June or July, 1930 (in Science). B. Confined Scholarship in Science. A Junior Science Scholarship of the value of £100 is offered for competition annually in June or July to candidates who have attended the preliminary science classes at this school. Candidates for these scholarships (male students only) must be under 20 years of age on August 1st of the year of the competition. C. Open Senior Science Scholarships: (1) A War Memorial Scholarship of the value of £100, (2) an Open Scholarship of the value of £80; both of these are awarded annually in September. Full particulars as to the scholarships may be obtained from the Dean of the Medical School. Junior prizes for general proficiency, £20, £15, £10; Hilton Prize for dissection, £5; Michael Harris Prize for anatomy, £10; Sands-Cox Scholarship for physiology, £15 for three years; Wooldridge Memorial Prize for physiology, £10; Beaney Prize for pathology, £34; Treasurer's Gold Medal in medicine, Treasurer's Gold Medal in surgery, and the Golding-Bird Gold Medal and Scholarship for bacteriology (£20), are awarded annually after competitive examination. The Gull Studentship in pathology, of the value of £250 per annum, the Beaney Scholarship in materia medica, of the annual value of about £50, and the Anderson Demonstratorship in clinical chemistry, value £175 per annum, are awarded without examination to enable research to be carried on in these subjects. An Arthur Durham Travelling Scholarship of £100 is awarded triennially. The Griffiths Demonstratorship in Pathology of the value of £320 per annum, and the Hilda and Ronald Poulton Fellowship, value £150 per annum, are awarded without examination.

An annual composition fee is paid by all students until a registrable qualification is obtained. Further information may be obtained from the Dean of the Medical School, Guy's Hospital, London Bridge, S.E.1.

KING'S COLLEGE HOSPITAL.

THE medical school of this hospital, which is situated at Denmark Hill, deals with the Final Examination subjects of the medical curriculum. The hospital was opened in 1913, and is one of the most modern and best equipped in England. The number of attendances in the casualty and out-patient departments during the year 1928 amounted to 285,348. In the education at the hospital a special feature has always been the individual attention given to each student. The studies are co-ordinated under the direction of senior members of the honorary staff, assisted by medical, surgical, obstetric, and pathological tutors. There are special departments for diseases of women and children, nervous diseases, ophthalmology, otology, laryngology and rhinology, dermatology, radiology, and physical treatment. The laboratory and pathological department are specially noteworthy.

Appointments.—Sixteen resident medical and surgical officers are appointed half-yearly, as well as dressers and clerks in the wards, out-patient departments, post-mortem rooms, and special departments. Each of the special

departments has several clinical assistants. There are three registrars and four tutors, all of whom receive salaries. The Clubs and Societies Union combines athletics, music, and other societies connected with the school, and provides also a common room.

Scholarships, etc.—At entrance: Science Scholarship, £50. At commencement of Final Studies: Anatomy and Physiology Scholarship, £50; Pathology Scholarship, £75; two Raymond Gooch Scholarships, each £60 a year for two years; two Burney Yeo Scholarships, each £80 (for Oxford and Cambridge students); Seaman Scholarships, £50 a year up to five years; Epsom College Scholarship, £50; Senior Scholarship, £40; Todd Prize, Tanner Prize, Class Prizes and Medals.

Fees.—The composition fee is 93 guineas if paid in one sum. Entrance fee of 10 guineas includes membership of the Clubs and Societies Union.

New Dental School.—This school was opened in October, 1923, and provides complete courses for dental degrees and diplomas. The director of dental studies is Dr. A. Livingston, M.B., Ch.B., M.D.S., L.D.S.

The calendar of the school can be obtained on application to the Dean, H. Willoughby Lyle, M.D., F.R.C.S., or to the Secretary of the Medical School, S. C. Ranner, M.A., King's College Hospital, Denmark Hill, S.E.5.

THE LONDON HOSPITAL.

THIS hospital, with its medical college and dental school, is situated in the Mile End Road, E.1. The hospital contains 839 beds, which are in constant use. During 1928, 14,698 patients passed through the wards and 96,928 out-patients received treatment. Of the latter number, 40,582 received treatment in the departments for diseases of the ear, nose, throat, eye, skin, and teeth, and in the pediatric, orthopaedic, venereal, radiological, electro- and physico-therapeutical, and inoculation departments. The number of major operations which were performed amounted to 7,649.

The hospital presents, therefore, a large field for clinical instruction, and in its wards and out-patient and special departments exceptional opportunities are afforded for acquiring an extensive and practical experience of all phases of disease.

A clinical unit in medicine, under the charge of a whole-time director, assisted by an assistant director, two assistants, and two house-physicians, provides for the more elaborate methods of diagnosis and treatment, and takes a leading part in the initiation and co-ordination of medical research. To each medical and surgical firm throughout the hospital there is attached a first assistant, who is responsible for instructing the clerks or dressers of the firm in elementary medicine and surgery, and who assists the honorary members of the firm in the preparation of their demonstrations. In the department of obstetrics and gynaecology there are two assistants and two resident accoucheurs. Special courses of lectures and demonstrations are arranged in medicine and surgery and in their ancillary subjects. Opportunities for research are provided under the supervision of the staff.

All the departments are modern and adapted for the teaching of all subjects in the various curricula. Special courses of instruction are held in preparation for the examinations of the University of London, for the Fellowship of the Royal College of Surgeons, and for the Membership of the Royal College of Physicians. Special entries can be made for the medical and surgical practice of the hospital. Two resident hostels are provided for the convenience of students. Recent additions to hospital and college buildings include a laboratory for the manufacture of certain preparations of radium. The athletic ground, of over thirteen acres, is at Higham's Park, and is open to all members of the Clubs Union.

Appointments.—The salaried appointments open to past students of the hospital are those of assistants to the medical unit; first assistants to the medical and surgical firms; obstetric registrar; assistants to the department of obstetrics and gynaecology; medical, surgical, and obstetric tutors; clinical assistants in the medical, surgical, ophthalmic, aural, light and skin, orthopaedic, and electrical departments, and in the Institute of Pathology. There are appointed annually 4 resident accoucheurs, 14 resident house-physicians and 22 resident house-surgeons, 14 resident receiving-room officers, 8 resident emergency officers, 8 clinical assistants to the medical out-patient department, and 16 clinical assistants to the surgical out-patient department, also paid and unpaid clinical assistants in the various special departments. In addition, there are numerous assistantships, clerkships, and dresserships in the departments of medicine, surgery, gynaecology, and obstetrics.

Scholarships and Prizes.—The following is a list of scholarships and prizes:—At entrance: Price Scholarship in science, £100. Two open scholarships, each of the value of £100. Scholarships open to students of Oxford and Cambridge Universities: (1) £100, anatomy and physiology; (2) £100, pathology. Entrance Scholarship in science, £50; Epsom Scholarship, "free medical education." After entrance: Buxton Prize in anatomy and physiology, £40; Lefheby Prizes in organic chemistry and chemical pathology, £25; Prizes in clinical medicine, surgery, and obstetrics and gynaecology, £20 each; Duckworth Nelson Prize in practical medicine and surgery, £10; Hutchinson Prize in clinical surgery, £60; Treves Prize in clinical surgery, £15; Sutton Prize in pathology, £20; K. E. D. Payne Research Scholarship in pathology, £20; Sir Andrew Clark Prize in clinical medicine and pathology, £14; T. A. M. Ross (prox. acc.) Prize in clinical medicine and pathology, £10 10s.; Anderson Prizes in elementary clinical medicine, £20; Dressers' Prizes, £20; Practical Anatomy Prizes, £10; Arnold-Thompson Prize in medical and surgical diseases of children, £15; Liddle Prize, £120; Francis Farmer Scholarship in dental surgery, £25; Harold Fink Prize in dental surgery, £8 8s. The "London" Prizes in dental surgery and pathology, £5 5s., and in dental prosthesis, £5 5s. Seven class examination prizes, each of the value of £3 3s., are offered for competition at the end of the courses of lectures in the dental curricula. Funds to the value of over £113,000 permit of financial assistance being given to students and graduates engaged in medical research.

Fees.—Entrance fee, 20 or 15 guineas, according to examinations passed; annual fee, 40 guineas.

Full information may be obtained from the Dean at the London Hospital Medical College, Mile End, E.1.

THE MIDDLESEX HOSPITAL.

THE school and hospital are in Mortimer Street, W.1, close to Oxford Circus, Goodge Street, and Great Portland Street stations. There are a gymnasium, common rooms, and restaurant within the hospital precincts, and an athletic ground within easy reach. The hospital contains over 450 beds, including a wing containing 92 beds for patients suffering from cancer. There are special wards for maternity and gynaecological cases, for mental cases, for cases of venereal disease, and for diseases of children and of the skin and eye.

The medical school, which includes the Bland-Sutton Institute of Pathology, the S. A. Courtauld Institute of Biochemistry, and the Barnato-Joel Laboratories, is completely equipped for teaching the entire medical curriculum, including the pre-medical subjects, chemistry, physics, and biology. The Bland-Sutton Institute, under the charge of the Professor of Pathology, contains large pathological and public health laboratories, and smaller rooms for original investigation as well as a pathological and anatomical museum. Bacteriological, chemical, and microscopical examinations of material from the wards, operating theatres, and out-patient departments are carried out in the laboratories, and senior students are eligible for clerkships in connexion with this work. Junior assistants in the pathological and bacteriological laboratories are elected annually from recently qualified students. Every facility is given for original research. The Biochemical Institute is under the charge of the Professor of Biochemistry, and contains teaching and research laboratories in addition to those devoted to the routine clinical work of the hospital. The Barnato-Joel Laboratories offer unrivalled opportunities for the study of cancer in both its clinical and pathological aspects.

Appointments.—Twenty-five resident appointments are open annually for competition among students of the hospital. The officers reside and board in the residential college free of expense. Two casualty medical and two casualty surgical officers, and two resident officers to the special departments, are appointed annually. Eight house-surgeons are appointed every year at intervals of two months, after examination; six house-physicians are also appointed annually at similar intervals. An obstetric and gynaecological house-surgeon is appointed every six months. Ten registrars are appointed annually. In the out-patient departments the appointments are: clerk and dresser to the physicians and surgeons to out-patients;

clerk in the departments for diseases of the skin and nervous diseases; dressers to the department for diseases of women, to the ophthalmic surgeon, to the throat and ear department, and to the dental surgeon. Extern midwifery clerks and post-mortem clerks are also appointed. The appointments are so arranged that every student may, during his course, hold all the out-patient and in-patient clerkships and dresserships. Students must have held an out-patient clerkship and dresserships before holding in-patient clerkships or dresserships. Non-resident qualified clinical assistants are appointed in the medical, surgical, skin, neurological, ophthalmic, throat and ear, odontological, children's, and electro-therapeutic out-patient departments.

Scholarships.—There are two Entrance Scholarships, value £100 each. Two annual Entrance Scholarships, of the value of £90 and £60 respectively, are open to students of the universities of Oxford and Cambridge who have completed the curriculum for, or passed the examinations in, anatomy and physiology. Students joining the school in the previous April are eligible. The Freer Lucas Scholarship is annually awarded on the nomination of the headmaster to a pupil of Epsom College who has passed the first examination for medical degrees (Preliminary Scientific Examination). There is also a scholarship, value £50, awarded annually to *students from New Zealand. In addition to the Entrance Scholarships*, there are numerous other valuable scholarships, prizes, and exhibitions open to students of the hospital, including the Brodrip Scholarships, value £60 and £40; Lyell Gold Medal and Scholarship, value £55 5s.; Freeman Scholarship, value £30; John Murray Gold Medal and Scholarship, value £25; Hetley Clinical Prize, value £25; Leopold Hudson Prize, value 11 guineas; and the Second Year's Exhibition, value 10 guineas.

The rebuilding of the hospital is being carried out without the loss of a single bed, or any disorganization of its clinics.

Fees.—(*a*) Pre-medical students: For one year or less, £21. (*b*) Students who have completed the Preliminary Science course: Entrance fee, 25 guineas, payable on joining the medical school; five annual fees of £45. The annual fee for further attendance at the medical school, if a registrable qualification has not been obtained, is £23. (*c*) Oxford and Cambridge and other students who have completed the Intermediate course: entrance fee, 15 guineas; three annual fees of £45; further annual fees as above. *These fees are inclusive and cover the cost of instruction in vaccination, fevers, etc., and also the subscription to the amalgamated clubs and hospital journal.*

Further information may be obtained from the *Dean or the School Secretary.*

St. Bartholomew's Hospital.

This institution fills one side of Smithfield and Giltspur Street, covering the greater part of a large island of ground separated practically from all other buildings; it is on the edge of the City, and easily reached from all parts of London. The hospital contains 757 beds. Extensive buildings, opened in July, 1907, occupy part of the ground acquired from the old Bluecoat School, and these materially enhance the attractions of the hospital as a place of medical study. The medical school buildings, including the library, the museum, and the chemical, biological, and anatomical departments, have now at their side a very large building, which includes club rooms for the Students' Union, a writing room, luncheon and dining halls, new quarters for the resident staff, and an out-patient department and accommodation for special departments of such large size as to be unsurpassed by any hospital in the kingdom. During the year 1909 a second block of new buildings was completed. These form the pathological department, and include, in addition to an extensive post-mortem room, large and well-equipped laboratories for clinical pathology, pathological histology, bacteriology, and chemical pathology, altogether forming the most complete pathological department in the country. A further large block in Giltspur Street was acquired in 1923, and has been equipped by the construction of new lecture theatres and extensive laboratories for physics, chemical physiology, experimental physiology, histology, and pharmacology. The new block of surgical wards and operation theatres, with accommodation for 250 patients, will be opened for use early in January, 1930. The Students' Union owns grounds of some ten acres in extent for recreative purposes at Winchmore Hill, which is easily accessible from the hospital.

Special classes are held for students preparing for the Preliminary Scientific and other examinations, for the M.B., M.D. of the Universities of Oxford, Cambridge, and London, and for the higher surgical degrees at the same universities, including the M.Ch.Oxon., M.Chir.Cantab., M.S.Lond., and F.R.C.S.Eng.

Clinical Units.—Special clinical units have been established in medicine and surgery, each under the charge of a professor and director, who devotes the whole of his time to the purpose of hospital practice, teaching, and research. In each unit there are an assistant director and four assistants, for whom special laboratory accommodation has been provided by a gift from the Sir William Dunn Trustees. The appointments of clerks and dressers are open to all students in these departments, and arrangements are made for all students to study in these units during a part of their clinical course.

Appointments.—Clinical clerks to the physicians and to the physician-accoucheur, and dressers to the surgeons and in the casualty department, are chosen from the students; clerks and dressers are also selected from the students to attend in the out-patient rooms, in the special departments (ophthalmic, orthopaedic, gynaecological, children's, laryngological, anal, dermatological, venereal, electrical, and dental), and in the post-mortem room. Chief assistants and clinical assistants are selected from qualified men appointed yearly to help in the general medical, surgical, and in special departments. Ten house-physicians and *ten house-surgeons are appointed annually. During their* first six months of office they act as "junior" house-physicians and house-surgeons, and receive a salary of £80 a year. During their second six months they become "senior" house-physicians and house-surgeons, and are provided with rooms by the hospital authorities, and receive a salary of £80 a year. A resident midwifery assistant, an ophthalmic house-surgeon, a house-surgeon to the skin and venereal department, and a house-surgeon for diseases of the throat, nose, and ear are appointed every six months, and are provided with rooms and receive a salary of £80 a year. Three resident administrators of anaesthetics are appointed—the senior for one year at a salary of £150, and two juniors for six months with a salary at the rate of £60 per annum—and all are provided with board and rooms. An extern midwifery assistant is appointed every three months, and receives a salary of £60 a year.

Scholarships.—Four Entrance Scholarships are annually awarded after examinations held in September. The subjects of examination and conditions of eligibility for these scholarships are: (1) One scholarship, value £75, in not fewer than two and not more than three of the following subjects: chemistry, physics, botany, zoology, physiology, pathology, and anatomy, limited to students under 25 years of age who have not entered on the medical or surgical practice of any London medical school. (2) One scholarship, value £100, in not fewer than three of the following subjects: chemistry, physics, botany, zoology, and physiology, limited to students under 21 years of age who have not entered on the medical or surgical practice of any London medical school. (3) An entrance scholarship in arts, of the value of £100, in mathematics; Latin or Greek, or French or German; a second language or chemistry or physics. (4) The Jefferson Exhibition in the same subjects as No. 3—of the value of £50. Candidates for Nos. 3 and 4 must be under 19 years of age. The total value of the scholarships and prizes is over £1,200 annually.

Further information and a handbook can be obtained on application to the Dean of the Medical College, St. Bartholomew's Hospital, E.C.1.

St. George's Hospital.

This school is at Hyde Park Corner, and is carried on in connexion with St. George's Hospital, an institution having a service of 436 beds, of which 100 are at the convalescent hospital at Wimbledon. It provides for the instruction of its students in the preliminary and intermediate subjects of the curriculum at the teaching centre of London University established at King's College. The school at Hyde Park Corner is devoted entirely to the teaching of clinical subjects, great attention being paid by the members of the staff to individual teaching. A number of special courses are given, in which the requirements of university and all other examinations receive careful attention.

The St. George's Hospital Club consists of an amalgamation club, with smoking and luncheon rooms on the hospital premises, and other students' clubs, with an athletic ground at Wimbledon. Students have the advantage of a well-filled library of medical and scientific books. A register of accredited apartments and a list of medical men and others willing to receive St. George's men as boarders may be seen on application to the Dean.

Appointments.—Two house-physicians, two house-surgeons, and two casualty officers are appointed every two months. The house officers reside and board in the hospital

free of expense. The casualty officers are non-resident, and receive salaries at the rate of £100 per annum. After the student has held a house appointment, the following are, among others, open to him: assistant resident physician at £250 per annum; assistant resident surgeon at £250 per annum; medical officer to the Atkinson Morley Convalescent Hospital at £300 per annum; medical registrarship at £200 per annum; surgical registrarship at £200 per annum; medical officer to the biochemical department at £100 per annum; assistant curatorship of the museum, £100 per annum; obstetric assistantship, resident, at £50 per annum; the post of resident anaesthetist at £100 per annum; the posts (three) of junior anaesthetist, each at £30 per annum.

Scholarships.—The following Entrance Scholarships and Exhibitions in anatomy and physiology and in general pathology are awarded in July to candidates who have passed the second M.B.London or corresponding examination; Senior William Brown Exhibition of the value of £120; Senior Scholarship of the value of 90 guineas; Junior William Brown Exhibition of the value of £80; Junior Scholarship of the value of £70; Devitt-Pendlebury Scholarship of the value of £50; and Exhibitions, each of the value of £40 and up to six in number. Other prizes to the value of £200 are awarded annually to the students of the hospital.

Fees.—First year (First M.B. or pre-medical course), £36 15s.; second and third years, £42 each. For the course of clinical study, in the fourth and subsequent years, entrance fee, £10 10s.; annual composition fee, £42. No entrance fee is payable by St. George's students who have studied at King's College.

Further information may be obtained from the Dean of the Medical School.

St. Mary's Hospital.

THIS hospital and medical school are situated close to Paddington Station (G.W.R.), having on one side a poor district of 500,000 persons, and on the other side the residential district of Kensington and Bayswater. The hospital contains 348 beds, and extensions recently completed have provided two new operating theatres. By a scheme of affiliation, for teaching purposes, of several neighbouring hospitals, the teaching facilities extend over 1,000 beds. By arrangement with the Lock Hospital, students take the courses of instruction in venereal diseases there. The athletic ground (ten acres) is situated at Wembley, and can be reached in twenty minutes by a constant service of trains.

Clinical Facilities.—Clinical units in medicine and surgery were established in 1920, and have now been formally recognized by the University Grants Committee, St. Mary's being one of the six medical schools in London which enjoy this privilege. In addition to the lying-in beds at St. Mary's, every student attends a short course at Queen Charlotte's Maternity Hospital (which is situated near to St. Mary's) before holding a post on the maternity district of the hospital.

Institute of Pathology and Research.—Students specially interested in pathology and bacteriology have singular advantages at St. Mary's. The Institute comprises seven special departments, the whole being under the personal direction of Sir Almroth Wright, F.R.S. Research scholarships of £200 each are awarded annually to students working in the departments of the Institute; and research beds are provided. Clerkships in pathology and bacteriology and chemical pathology, lasting for a period of three months, are open to students of the fifth year, and enable them to carry out the pathological and bacteriological investigations of the wards, and learn the necessary technique under supervision. Seventy-two of these posts are available annually. Numerous appointments are open to newly qualified members of the medical school, including ten salaried posts, with salaries varying from £200 to £750 per annum.

Complete Curriculum.—The medical school provides complete courses of instruction, and students can join at once on passing a preliminary examination in arts. Terms begin in October, January, and April.

Entrance Scholarships.—Two Entrance Scholarships of £210 each and one of £26 5s. are awarded annually in July by nomination on the lines of the Rhodes Scholarships. The Geraldine Harmsworth Scholarship (£200) and one or more University Scholarships of £200 are awarded annually in July.

Fees.—Composition fees for entire curriculum (6 years), £205 in one sum, or £215 by five annual instalments. Composition fee for clinical curriculum (3 years), 95 guineas in one sum, or 100 guineas by two annual instalments. As an alternative, students may pay an annual fee of 40 guineas, with an entrance fee.

St. Thomas's Hospital.

THIS school and hospital are situated in Lambeth, on the south bank of the Thames, facing the Houses of Parliament, and form one of the well-known architectural features of London.

The school buildings, which are separated from the hospital by a quadrangle, comprise lecture theatres, laboratories, and classrooms well adapted for the modern teaching of large bodies of students in the subjects of the medical curriculum. A splendid library and reading room and a complete museum are open to all students from 9 a.m. to 5 p.m., on Saturdays to 1 p.m. St. Thomas's House, the new Students' Club recently opened, comprises spacious dining and club rooms, etc., and provides accommodation for some sixty resident students. The terrace affords facilities for exercise and recreation. The sports ground, more than nine acres in extent, is at Chiswick. It can be reached in forty minutes from the hospital; it is admirably adapted for football, cricket, lawn tennis, and athletic sports.

The hospital proper contains 644 beds. In addition to the ordinary provisions of a great hospital there are connected with the out-patient department physicians' and surgeons' rooms provided with ample sitting accommodation, so that students are enabled to follow closely the practice and teaching of the out-patient staff. There is a full complement of special departments, and connected with the hospital a special tuberculosis department gives opportunity for instruction of students. There is a clinical theatre, centrally situated, so as to facilitate the illustration of lectures by patients from the wards and out-patient room; it is arranged also for lantern demonstrations. A clinical unit in medicine has been established. The maternity ward, containing 21 beds, gives students full facilities for maternity training, under supervision, within the precincts of the hospital. This obviates any necessity for supplementary instruction elsewhere, and fully prepares the student for the extern maternity practice of the hospital district. The revised regulations of the examining bodies can thus be fully complied with.

Appointments.—All hospital appointments are open to students without charge. A resident assistant physician and a resident assistant surgeon at £225 each per annum, and a resident anaesthetist at £200 per annum, are appointed annually. Three hospital registrars—one medical and two surgical—at an annual salary of £250 each, rising by £25 to £300, are appointed yearly. The tenure of these offices may be renewed for a term not exceeding three years. A pathological registrar to the department of obstetrics and gynaecology (at an annual salary of £250), an ophthalmic registrar (at an annual salary of £200), and an orthopaedic registrar (unpaid) are appointed yearly. Ten resident casualty officers and anaesthetists (including two senior) are appointed every six months. Seven house-physicians (including two obstetric house-physicians and one house-physician to the department of diseases of children) and nine house-surgeons (including two ophthalmic house-surgeons, one orthopaedic house-surgeon, and two house-surgeons to the ear, nose, and throat department) are appointed every six months. Thirty-six or more clinical assistants in the special departments are appointed every three months, and hold office for six months if recommended for re-election. Clinical clerkships and dresserships to the in-patient and out-patient departments are available to the number of 400 each year.

Scholarships.—There are five Entrance Scholarships: two in arts, giving one year's free tuition; one of £150 and one of £60, in chemistry, physics, and biology, for students who have not received instruction in anatomy or physiology; one of £100 in any two of the following subjects: anatomy, physiology, chemistry, or pathology, for students who have completed their examinations in anatomy and physiology for a medical degree in any of the universities of the United Kingdom or the Colonies, and have not entered as clinical students in any London medical school. The money value and subjects of examination of the remainder are as follows: (*a*) William Tite Scholarship for second-year students, £25; (*b*) and (*c*) Musgrove Scholarship or (alternately) Peacock Scholarship, each for third-year students and tenable for two years, £35 each; (*d*) Mead Medal, medicine, pathology, and hygiene; (*e*) Wainwright Prize, medicine; (*f*) Toller Prize, medicine; (*g*) Cheselden Medal, surgery and anatomy; (*h*) Clutton Memorial Medal in clinical surgery, biennial; (*i*) Beaney Scholarship, £50 biennially, surgery and surgical pathology; (*j*) Solly Medal and Prize, biennially, reports of cases; (*k*) Sutton Sams

Prize, biennially, reports of cases; (*l*) Bristowe Medal, pathology and morbid anatomy; (*m*) Hadden Prize, pathology and morbid anatomy; (*n*) Grainger Testimonial Prize, £31 10s., anatomy and physiology; (*o*) Louis Jenner Research Scholarship, tenable for two years, £60 annually, pathology; (*p*) School Council Research Scholarship, £250 per annum; (*q*) John and Temple Research Scholarship, value £450 per annum (children).

Fees.—The annual fees are: For each year of study, £50. These fees cover all tutorial classes, but do not include instruction in infectious fevers, pharmacy, and vaccination. A limited number of qualified practitioners are permitted to attend the hospital practice on terms which may be ascertained from the Medical Secretary.

Special courses of instruction are given for various examinations, and a register of lodgings is kept at the school. Further information may be obtained from the Medical Secretary of the School, St. Thomas's Hospital, Albert Embankment, S.E.1.

University College Hospital.

The school, which forms part of the corporation of University College Hospital, is in immediate proximity to the hospital in University Street, and opposite University College. It comprises departments of medicine, surgery, midwifery and gynaecology, pathology including morbid anatomy, chemical pathology, biochemistry and bacteriology, cardiography, forensic medicine, mental physiology and mental diseases, dental surgery, practical pharmacy, and other departments for the study of special diseases, such as those of the eye, skin, ear and throat, venereal diseases, and for instruction in anaesthetics, electro-therapeutics, and skiagraphy. The hospital and school have acquired the National Dental Hospital and College as their dental departments, thus providing every facility for the study of dental subjects. The Royal Ear Hospital has also been amalgamated as the Ear, Nose, and Throat Department, and a new hospital for in- and out-patients, close to University College Hospital, is completed.

The school thus provides the final course of study for the degrees of the Universities of Oxford, Cambridge, London, Durham, and other British universities, and for the diplomas of the Royal Colleges of Physicians and Surgeons in medicine and in dental surgery, and the Licence of the Society of Apothecaries. Special bacteriological classes are also held in preparation for the various diplomas in public health. Each department is also equipped for more advanced work, and provides facilities for research.

Clinical units in medicine, surgery, and obstetric medicine are now in operation. The whole-time directors of the units are concerned with the organization of the teaching generally, but the honorary staff is responsible for the largest share of the teaching in the wards and out-patient department of the hospital.

The new buildings of the obstetric hospital of 74 beds (rendered possible by the Rockefeller benefaction), the new Residents' House (with accommodation for 33 residents and students), the extension of the Nurses' Home, and the new research laboratories for the Medical School, are now finished and in full occupation.

Appointments.—The qualified appointments, in addition to a number of posts as house-physicians and house-surgeons and obstetric assistants, include the appointments of resident medical officer, medical registrars, surgical registrar, obstetric officer, Harker Smith radium registrar, ophthalmic registrar, casualty medical officers, casualty surgical officers, assistants in ear, nose and throat, skin and venereal diseases departments, and house anaesthetists.

Scholarships.—The following scholarships and prizes are open to competition: Two Entrance Exhibitions of 112 guineas each, awarded after a competitive examination in any two of the following subjects: anatomy, physiology, or general pathology; Radcliffe Crocker Travelling Scholarship in dermatology for one year, value about £280; the Graham Scholarship in pathology of a sum not exceeding £400 per annum; Leslie Pearce Gould Research Scholarship in surgery for one year, value about £200; the Atkinson Morley Scholarship of £45 a year for three years, awarded after examination in the theory and practice of surgery; the Atchison Scholarship of £55 a year for two years for general proficiency in medical studies; the Magrath Clinical Scholarship, value about £150; the Filliter Exhi[illegible] £30; the Percival Alleyn Prize for the [illegible] by research, value about £75; the Gral [illegible] arch work; four Fellows Medals in clinical medicine; Liston Medals in clinical surgery; the Bruce Medal in pathology and surgery; two Tuke Medals in pathology; and the Erichsen Prize for practical surgery.

Fees.—The fee for the full course of final studies at the school is 112 guineas if paid in one sum, or 115 guineas if paid in two instalments. Fees for vaccination, fevers, and pharmacy not included.

Particulars of general and special courses can be obtained on application to the Dean of the Medical School, University College Hospital, University Street, W.C.1.

Westminster Hospital.

The school, with its hospital situate in Broad Sanctuary, opposite Westminster Abbey, provides for the education of its students in the preliminary and intermediate subjects of the University of London at King's College. The rest of the work is done in the school buildings near the hospital. The number of in-patients averages 3,500 and out-patients upwards of 30,000 annually, and the hospital and school afford ample facilities for instruction in all branches of medicine and surgery.

Appointments.—A medical and surgical registrar are appointed annually, each with a salary of £150, and an obstetric registrar with a salary of £50. A senior resident and casualty officer, salary £104 per annum and board, appointed for six months, may be extended for a further period of six months. Three house-physicians, three house-surgeons, three assistant house-physicians, three assistant house-surgeons, and a resident obstetric assistant are appointed after examination, and are provided with rooms, commons, and salary of £52 per annum, except the assistant house-physicians and the assistant house-surgeons, who are provided with commons only. The assistant house-physicians, after three months' service, become house-physicians for a further period of six months, and the assistant house-surgeons, after three months' service, become house-surgeons for a further period of six months. Two house-anaesthetists are appointed for three months, non-resident, salary £50 per annum. Clinical assistants to the assistant physicians and assistant surgeons, and to the officers in charge of special departments, are appointed from among the qualified students. Every student must perform the duties of out-patient dresser for three months, and afterwards hold the office of in-patient dresser for three months. He is also required to serve two terms of three months each as medical clinical clerk to the in-patient physician and one term as gynaecological clinical clerk. Two pathological clerks are appointed every three months to assist in the post-mortem room. No student is eligible as an in-patient dresser or clinical clerk until he has passed the Second Examination of the Conjoint Board, or an equivalent examination. Clerks and dressers in the special departments of hospital practice are periodically appointed. So far as vacancies permit, students of other hospitals are admitted to in-patients' dresserships or clerkships.

The governors of the hospital have now completed the extensive improvements and alterations to the hospital, which render it a still more efficient teaching institution, with an increased number of beds.

The athletic ground is situated at Tooting, and can be reached in twenty minutes from the hospital.

Scholarships.—The following open scholarships are offered for competition during the year 1929-30: In the winter session two scholarships in anatomy and physiology, £75 each. In the spring two scholarships in anatomy and physiology, £75 each. A certain number of scholarships have been allotted to universities of England, Wales, and the Colonies, and to public schools. These scholarships are awarded entirely on the nomination of the Principal of the university or school.

Fees.—The annual composition fee is £40. An entrance fee of 10 guineas is payable by all students—namely, primary and intermediate students, £10 10s.; students entering for the final subjects, £8 8s. These fees include subscriptions for membership of the Clubs Union.

Further information and a prospectus can be obtained on application to the Dean at the Westminster Hospital, Westminster, S.W.1.

London (Royal Free Hospital) School of Medicine for Women.

The school is situated at 8, Hunter Street, Brunswick Square, W.C.1, close to the Royal Free Hospital. It is, like all the other London schools which have so far been mentioned, one of the constituent schools of London University. The laboratories are extensive and well lighted, and are fully equipped for the examination courses of and are fully equipped for the examination courses of the University of London and the Royal Colleges of

Physicians and Surgeons. Research laboratories are attached to all departments. A large, well-equipped library, common room, Union Room, and refectory are provided for the use of students. Resident accommodation for 78 students is provided in students' chambers attached to the school.

The Royal Free Hospital, Gray's Inn Road, W.C.1, has 268 beds, all of which are available for clinical instruction. A new block contains the obstetrical and gynaecological unit, which controls 68 beds. A large maternity district is served from the unit with a separate maternity hostel in the Essex Road, Islington. There are separate departments for diseases of the eye, ear, and skin, children and infant welfare, venereal diseases, orthopaedic surgery, massage, light, electrical and x-ray work, dentistry, and casualty. The instruction given covers the full curriculum for the M.B., B.S. degrees of the University of London, including first medical courses. Students attend the practice of one of the fever hospitals of the Metropolitan Asylums Board and receive special instruction in lunacy at Horton Mental Hospital, Epsom; they are also admitted to the practice of a number of special hospitals, and hold clerkships and dresserships at the Elizabeth Garrett Anderson Hospital, the Cancer Hospital, Hospital for Sick Children, Great Ormond Street, the National Hospital for Nervous Diseases, the South London Hospital, and the Royal Ophthalmic Hospital. The work of the school includes preparation for the Primary Fellowship examination, and also for the Medical School and general hospital course for dental students.

Appointments.—Qualified students of the school can obtain appointments as house-physicians and house-surgeons, obstetric assistants, surgical, gynaecological, and medical registrars, assistant pathologists, assistant anaesthetists, medical electrician, skiagrapher, and clinical assistants and demonstrators in various subjects.

Scholarships.—The Isabel Thorne Entrance Scholarship, value £30, the St. Dunstan's Medical Exhibition, value £60 a year for three years, which may be extended to five years, the Alfred Langton Scholarship of £50 a year for two years, the Flora Murray Bursary of £50, and the Mabel Sharman-Crawford Scholarship, value £20 a year for four years, are offered for competition in each year. The Sir Owen Roberts Memorial Scholarship of the value of £75 a year for four years, the Mrs. George M. Smith Scholarship of the value of £50 a year for three years, which may be extended to five years, the Dr. Margaret Todd Scholarship of the value of £37 10s. a year for four years, and the Sarah Holborn Scholarship of the value of £20 a year for three years, which may be extended to five years, are awarded in alternate years. The School Jubilee Bursary of £50 a year for three years is offered every third year. The Bostock Scholarship, value £90 a year for two or four years, is awarded by the Reid Trustees on the result of an examination held in May by the University of London every fourth year. The holder of the scholarship must enter the London School of Medicine for Women. The Lieutenant Edmund Lewis and Lieutenant Alan Lewis Memorial Scholarship, of the value of £25 a year for four years, is awarded every fourth year. The John Byron Bursary of £20 a year for two years, the Julia Ann Hornblower Cock Prize of £60, the Helen Prideaux Prize of £60, the Mabel Webb Research Scholarship of £30 for two years, the Fanny Butler Scholarship of £16 a year for four years, together with many other scholarships and prizes, are offered on sundry conditions. The Dr. Edith Pechey-Phipson Post-Graduate Scholarship of £100 is awarded annually. Altogether the school offers annually £1,350 in scholarships. Various missionary societies also offer scholarships on certain conditions, and assist women who wish to go to India and other countries as medical missionaries.

Fees.—Courses for the University of London degrees and the diplomas of the Conjoint Board in England, and other qualifications: £50 per annum throughout the course.

The Students' Union exists to promote corporate action of the students on matters of common interest, to promote and maintain athletic and other clubs, and to issue a school magazine. All students are required to become members of the Union. The students' sports ground, which consists of a freehold property of seven and a half acres, is situated at Sudbury.

Further information can be obtained from the Warden and Secretary.

King's College.

In the Faculty of Medical Science instruction is given in the preliminary and intermediate subjects of the first and second examinations leading to the degree of M.B., B.S. of the University of London, of the corresponding examinations of other universities, and of the Conjoint Examining Board of the Royal Colleges of Physicians and Surgeons. The courses are open to women students on the same terms as to men.

Regular students who have completed their preliminary and intermediate examinations proceed to a hospital to pursue their studies for the final examinations. Special courses in anatomy and physiology are held in preparation for the primary examinations for the Fellowship of the Royal College of Surgeons.

A course for the degree of the University of London and for the diploma of the Royal College of Surgeons in dental surgery is given in conjunction with King's College Hospital Medical School.

Scholarships.—The entrance scholarships are: (1) Two Warneford Scholarships, each £30 for four years; subjects—selected from mathematics, classics, divinity, and science. (2) One Sambrooke Scholarship of £30 for three years; subjects of examination selected from mathematics, classics, and science. The holders of the preceding awards must proceed to King's College Hospital. (3) Worsley, £100, paid in five annual instalments. (4) Rabbeth Scholarships, value £30 and £15, in July, for the best student of the first year. (5) Second year's scholarship, value £20, for the best student of the second year. (6) Daniell Scholarship, £40, awarded on the results of the University Honours Examination. (7) The Layton and Berridge Studentships, each £150 per annum, and (8) numerous prizes.

Full information as to admission, fees, and scholarships can be obtained from the Dean of the Faculty of Medical Science, King's College, Strand, W.C.2.

University College.

This institution, one of the principal component parts of the University of London, possesses a Faculty of Medical Sciences whose work covers all the subjects included in the group commonly known as the preliminary medical sciences—namely, physics, chemistry, botany, and zoology; and also the intermediate medical sciences—namely, anatomy (including embryology and histology), physiology, biochemistry, and pharmacology. The new anatomy building, provided by the munificent gift of the Rockefeller Foundation of New York, was opened on May 31st, 1923, by His Majesty the King. This building forms part of the block which includes physiology and pharmacology. Research work is undertaken in all the above-named departments. The College undertakes the education of students in all the subjects mentioned, leaving them free to complete their education in the strictly professional subjects—medicine, surgery, and the like—at any one of the recognized schools of advanced medical studies. The work is somewhat differently arranged, according to whether the student has in view the degrees of the University of London or the diplomas of the Royal Colleges. In either case the whole work to be done is divided into courses devised to meet the requirements of different examinations, and students can join the College for any of them. Women students are admitted to all courses on the same terms as men. The general arrangements for the benefit of students include membership of the Union Society or the Women's Union Society with the College gymnasium and the athletic grounds. There is also a collegiate residence for about fifty-five men students at Ealing and for about seventy women students at Byng Place, Gordon Square.

Scholarships.—The scholarships and exhibitions obtainable include the Bucknill Scholarship, value 160 guineas, in chemistry, physics, botany, and zoology (the successful student must complete his work at University College Hospital Medical School), two entrance exhibitions in the same subjects, each of the value of 55 guineas, a Faculty of Medical Sciences Entrance Scholarship, value £30 a year, for three years; and the Bayliss-Starling Memorial Scholarship (physiology and/or biochemistry), £120.

Fees.—The fees for the courses covering the work of the First Examination for medical degrees of the University of London, and in both parts of the Second Examination, amount to 115 guineas. The fees for the courses covering the corresponding examinations held by the Conjoint Board in England also amount to 115 guineas. These fees may be divided into payments for the different courses which it may be desired to take out, but do not cover tuition for more than a stated period.

A handbook specially relating to this faculty may be obtained on application to the Secretary of University College, Gower Street, London, W.C.1.

THE PROVINCES.

There are in England and Wales, not counting London, ten medical schools, each supplying instructions in the full medical curriculum. Accounts of them here follow. In several cases information is appended about hospitals other than those directly connected with the school in question; such hospitals, officially and unofficially, play a part in the

education which the students of the school receive, and in any case serve as places of additional or post-graduate study.

Oxford and Cambridge.

At both Oxford and Cambridge there are medical schools which furnish unsurpassed opportunities for obtaining a good knowledge of the preliminary sciences and of anatomy, physiology, and pathology. The laboratories are excellently furnished, and the teaching staffs most distinguished. Both schools provide a full medical curriculum, and there is no essential reason why the student should not complete his career at either of them; but this is not commonly done, and is never, in the ordinary way, advised by the university medical authorities. The local hospitals—the Radcliffe Infirmary at Oxford and Addenbrooke's Hospital at Cambridge—though well equipped, are comparatively small. Students are therefore encouraged, as soon as they have completed the earlier examinations and taken a degree in arts, to join one of the London medical schools, and thus spend the time of their preparation for the final examinations in a city where the opportunities for gaining clinical knowledge are greater and more varied. A considerable proportion of Oxford and Cambridge medical students take the London Conjoint diplomas before graduating in medicine and surgery at their own university. The experience gained by holding resident hospital appointments is naturally of much advantage when sitting for the Final M.B. examination and when engaged in composing a thesis.

Birmingham.

The school in this city is carried on by the Medical Faculty of the University of Birmingham, its students having an adequate number of good laboratories, classrooms, and other necessaries devoted to their use by the university. The clinical work is done at the General and Queen's Hospitals, which are amalgamated for the purpose. Together they have upwards of 600 beds for medical, surgical, and special cases, with an array of special departments of all kinds, including one for lying-in women. Clinical instruction is given in the wards and out-patient and special departments daily, and formal clinical lectures are delivered weekly throughout the winter and summer sessions. Special tutorial classes are also held alike for the degrees of Birmingham and some other universities and for the diplomas of corporations.

Appointments.—The large number of appointments open to past or other students includes the following:—At the General Hospital: surgical registrar, £200 a year; one resident medical officer, salary £155 a year; one resident surgical officer, salary £180 a year; one assistant resident surgical officer, salary £100 a year; one resident pathologist, salary £70 a year; two visiting anaesthetists, salary £50 a year; one resident anaesthetist, salary £70 a year; four house-surgeons, office tenable for nine months, £70 a year; one house-surgeon to the gynaecological and one to the special departments, each tenable for six months, £70 a year; four house-physicians, post tenable for six months, £70 a year. At the Queen's Hospital: one medical registrar and one surgical registrar, non-resident, tenable for three years, renewable, salary £100 per annum; three house-physicians, three house-surgeons, and one obstetric and ophthalmic house-surgeon, tenable for six months, salary £70 per annum, with board, lodging, and washing; one casualty house-surgeon, tenable for three months, salary £70 per annum, with board, lodging, and washing. At the Maternity Hospital: three house-surgeons, salary £50 a year. At the City Workhouse and Workhouse Infirmary: five resident medical officers. At the Birmingham General and Branch Dispensaries: twelve resident surgeons. At the Birmingham Mental Hospitals: five assistant medical officers. At the City Fever Hospitals: three assistant medical officers. At the Children's Hospital: one resident surgical officer, one resident medical officer. At the Birmingham and Midland Eye Hospital: four resident surgeons. At the Orthopaedic and Spinal Hospital: two clinical assistants (non-resident). At the Ear and Throat Hospital: one house-surgeon, £70 a year; four clinical assistants (non-resident). Four non-resident Poor Law appointments are in the gift of the Board of Guardians.

Scholarships.—There are numerous money and other awards for students of sufficient merit, among them being the following: The Walter Myers Travelling Studentship of £300, offered each alternate year for research work and tenable abroad; the Sands-Cox Scholarship of £42 (an entrance scholarship in the Faculty of Medicine, awarded on higher school certificate examination of the Joint Matriculation Board (July)); four Queen's Scholarships of £10 10s. each, awarded annually at the second (Part II), third, fourth, and final university examinations respectively; one or more Sydenham Scholarships, allotted on entrance to students who are the sons of deceased medical men; the Ingleby Scholarships (two) of £10 for proficiency in midwifery and diseases of women; the Arthur Foxwell Memorial Gold Medal (clinical medicine); the Sampson Gamgee Memorial Medal for surgery (Final M.B.); and the Peter Thompson Prize in anatomy (value about £6) for students in their third university year. There is also a scholarship of £46 17s. 6d. for students proceeding to a degree in dental surgery. University Clinical Board Prizes are awarded annually as follows: Senior Medical Prize, Gold Medal; Senior Surgical Prize, Gold Medal; Midwifery Prize, Gold Medal; Junior Medical Prize, Silver Medal; Junior Surgical Prize, Silver Medal.

Fees.—The composition fee for university classes is £106 5s. This covers all the work required for the degrees of Birmingham and some other universities, and for the ordinary qualifications of licensing corporations, but not the additional courses required for the Fellowship of the Royal College of Surgeons of England, the diploma and degrees of the university in State medicine, and some other special work. The total cost for the six years' curriculum, including hospital and examination fees, is estimated at £201 4s. 6d.

Other information should be sought from the Dean of the Medical Faculty, University, Edmund Street, Birmingham.

Bristol.

The school is carried on by the Faculty of Medicine of the university, and provides full instruction for all its degrees and for the diploma in dental surgery.

Clinical Instruction.—The allied hospitals (Bristol Royal Infirmary and Bristol General Hospital) have between them 663 beds and extensive out-patient departments, special clinics for diseases of women and children, and those of the eye, throat, and ear, in addition to large and well-equipped departments for dental work and large out-door maternity departments. At each of these institutions there are well-arranged pathological museums, post-mortem rooms, and laboratories for morbid anatomy. There are also laboratories for work in clinical pathology, bacteriology, and cytology, in which special instruction is given in these subjects. Departments are provided and well equipped for x-ray work, both for diagnosis and treatment, for electro-cardiography, and for the various forms of electrical treatment, including high-frequency currents, electric baths, Finsen light treatment, and massage. The students of the school also attend the practice of the Royal Hospital for Sick Children and Women, containing 100 beds, and that of the Bristol Eye Hospital, with 40 beds. In addition, by the kind permission of the Bristol Board of Guardians, students may attend the clinical practice at Southmead Hospital, which has 556 beds. The total number of beds available for clinical instruction is therefore 1,359.

Appointments.—(1) Undergraduate: Medical clerkships, surgical dresserships, also ophthalmic, obstetric, pathological, dermatological, ear, nose, and throat clerkships, are tenable at the Bristol Royal Infirmary and the Bristol General Hospital. In these institutions the dressers reside in rotation free of charge. (2) Post-graduate: At the Bristol Royal Infirmary: four house-surgeons, one casualty house-surgeon, two house-physicians, one house-physician for cancer research wards, one resident obstetric officer, one ophthalmic and gynaecological house-surgeon, one ear, nose, and throat house-surgeon, one assistant to the senior resident medical officer, who also acts as house-surgeon and house-surgeon to the skin department, and one dental house-surgeon. All these appointments are for six months. Salary in each case at the rate of £60 per annum, with board, apartments, and laundry, except the casualty house-surgeon, who receives £80 per annum. From the resident medical officers a senior resident medical officer is appointed at a salary of £200 per annum. At the Bristol General Hospital: senior resident medical officer, £250 per annum; casualty house-surgeon, £80 per annum; two house-physicians, £80 per annum; two house-surgeons, £80 per annum; resident obstetric officer, £80 per annum; house-surgeon to special departments, £80 per annum; dental

house-surgeon (non-resident), £300 per annum. All these appointments are for six months, except that of senior resident medical officer, which is for two years.

Scholarships.—The following are among the scholarships and other awards open to students of the school: The Ashworth Hallett Scholarship, value £40, open to women only; two Martyn Memorial Pathological Scholarships of £10 each; the Tibbits Memorial Prize, value 7 guineas, for proficiency in practical surgery; the Committee's Gold and Silver Medals, for fifth-year students for general proficiency; the Augustin Prichard Prize, value about 6 guineas, for proficiency in anatomy; the Henry Clark Prize, value 11 guineas, for proficiency in gynaecology; the Crosby Leonard Prize, value 6 guineas, for proficiency in surgery; the Suple Surgical Prize, a gold medal and 7 guineas; the Suple Medical Prize, a gold medal and 7 guineas; the Henry Marshall Prize, value £12, for dressers; the H. M. Clarke Scholarship, value £15, for proficiency in surgery; the Sanders Scholarship, value £22 10s., for general proficiency; the Barrett-Roué Scholarship for proficiency in diseases of the nose, throat, and ear, or skin, value £17; Lady Haberfield Scholarship, value about 25 guineas; Phyllis Siepman Prize for proficiency in diseases of children, value £25. Bristol City Senior Scholarships and the Senior Scholarships offered by the counties of Gloucestershire, Somerset, Wilts, Devon, etc., are tenable in the university.

Some of the Fellowships awarded by the Colston Research Society for research in the university are allotted to the Faculty of Medicine.

A Beaverbrook Fellowship tenable for three years is open to all members of the university holding a medical qualification.

Fees.—The fee for all the courses required for the medical curriculum, including hospital practice, is 205 guineas, paid by annual instalments.

Further information as to scholarships, curricula, and fees can be obtained from the Dean of the Faculty of Medicine, or the Registrar of the University, Bristol.

UNIVERSITY OF DURHAM COLLEGE OF MEDICINE.

THIS, the Medical School of the Faculty of Medicine of the University of Durham, is in the neighbouring city, Newcastle-upon-Tyne. Its classes and lectures are arranged to meet the requirements of the university in all the degrees which the latter grants, and also those of the other examining bodies. The students do their work in the preliminary sciences at Armstrong College, also part of the university. Hospital practice is carried out at the Royal Victoria Infirmary, a general hospital containing more than 550 beds, where there are facilities for the study of the various special subjects. Students do their practical midwifery at the Princess Mary Maternity Hospital, which contains 90 beds, is thoroughly up to date, and has an annual indoor and outdoor attendance on 3,000 cases. In the Heath wing of the school itself there is a gymnasium and a set of rooms for the separate use of the students. A new bacteriological department has been erected adjacent to Armstrong College.

Post-Graduate Instruction.—A comprehensive series of post-graduate courses has been arranged to enable practitioners to take advantage of the facilities for laboratory work and clinical study which are afforded by the College, the Royal Victoria Infirmary, and other associated hospitals, and in order to meet the varied requirements of practitioners there are general and special courses in the winter and summer session as well as an intensive course in the summer vacation.

Students' Union.—A Students' Union has been erected and furnished at a cost of over £40,000, and is in daily use. Separate accommodation (non-residential) is provided for men and women students.

Appointments.—Pathological assistants, and assistants in the eye department, throat and ear department, and department for skin diseases, are elected periodically. Clinical clerks and dressers are appointed every three months.

Scholarships.—University of Durham Entrance Scholarship, £25 a year for four years; Pears Entrance Scholarship, £40 a year for three years (awarded every third year); Heath Entrance Scholarship (from Kepier Grammar School), £60 (renewable); Province of Durham Masonic (Entrance) Scholarship, £60 (renewable); Heath Scholarship for surgery, £200, available every second year; Rutherford Morison Surgical Scholarship, £180, available every third year.

The following scholarships are tenable for one year—namely, Tulloch Scholarship for elementary biology and organic chemistry, £20. Dickinson Scholarship for medicine, surgery, midwifery, and pathology, Gold Medal and £20; Charlton Scholarship for medicine, £25; Gibb Scholarship for pathology, £28; Luke Armstrong Scholarship for comparative pathology, £25; Stephen Scott Scholarship for surgery, £40; Philipson Scholarships for highest marks in Final M.B., B.S. Examination, two of £18 each; Goyder Memorial Scholarship for clinical medicine and clinical surgery, interest on £325; Gibson Prize for midwifery and diseases of women and children, £10; Turnbull Prize and Silver Medal for surface anatomy; Outterson Wood Prize for psychological medicine, £10; and Sewell Memorial Prize and Silver Medal for clinical pathology. At the end of each session a prize of books is awarded in each of the regular classes.

Fees.—The composition fee for lectures at the college is £140. Composition fee for hospital practice, £46, *plus* £2 2s. yearly for three years, payable to the Committee of the Royal Victoria Infirmary. Other information should be sought from the Dean of the College, University of Durham College of Medicine, Newcastle-upon-Tyne.

LEEDS.

THE School of Medicine—which is open to both male and female students—in this city forms the teaching centre of the Medical Faculty of the University of Leeds, and is situated in immediate proximity to the General Infirmary, where students sufficiently advanced receive their clinical instruction. The buildings were opened in 1894, and contain excellent dissecting rooms, well-arranged laboratories for physiology, pathology, and bacteriology, three lecture theatres, and several similar classrooms. In addition, there are a library and reading room and museums of pathology and anatomy. The comfort of the students is secured by means of common rooms and a refectory. Extensions of the medical school buildings are at present in course of erection, and an Institute of Pathology is to be built in the near future on an immediately adjacent site. The General Infirmary has 632 beds, and includes gynaecological and ophthalmic wards, special children's wards, and a large out-patient department. The Ida and Robert Arthington Semi-convalescent Hospitals, Cookridge, attached to the infirmary, have 88 beds. The West Riding Mental Hospital at Wakefield is available for the study of mental diseases. Students can, in addition, attend the practice of the Leeds Public Dispensary, the Hospital for Women and Children, and the Leeds Maternity Hospital.

Appointments.—Physicians' clerks and surgical dressers are appointed every six months; clerks in the children's department, orthopaedic dressers, ophthalmic and aural dressers, gynaecological ward clerks, maternity clerks, assistant physicians' clerk, dermatological clerks, assistant surgeons' dressers, dressers in the casualty rooms, junior and senior post-mortem clerks, laboratory assistants and dressers in the venereal clinic every three months. After graduation a considerable number of resident and other appointments become available in the Leeds General Infirmary; Leeds Public Dispensary, Hospital for Women and Children, West Riding Mental Hospital, etc., occupying periods of from six to twelve months at rates varying from £20 to £150 per annum.

Scholarships.—The university awards annually a scholarship in the form of a free admission to the lectures and classes given in the university, which are covered by the composition fee. The university also awards a scholarship on the results of the first examination, of the value of £68, in the form of a free admission to the clinical teaching of the infirmary.

Fees.—It is estimated by the authorities that the approximate cost of medical education to a student in this university is £324, *plus*, of course, the expenses of living during the five and a half years covered by the curriculum. The composition fee for the course for the first, second, and third examinations, and for the clinical work at the infirmary, is £237. The composition and clinical fee for those who have passed the second examination is £150.

Further information can be obtained from the Academic Subdean or Clinical Subdean, School of Medicine, Leeds.

LIVERPOOL.

THE Medical School of this city is part of the university, and, owing to the enlightened liberality of several men of wealth, is exceptionally well provided with special laboratories, as well as with ordinary spacious and well-equipped classrooms and laboratories for the instruction of students proceeding to medical degrees and diplomas in special and ordinary subjects. All the laboratory and other rooms are situated close to one another and intercommunicate, together forming large blocks of buildings. The work of students throughout all stages of their career is arranged upon very satisfactory lines, and the teaching hospitals, of which a list is given below, have amalgamated to form the clinical school of the university.

Appointments.—The nature of the appointments open to past and other students at this school will be gathered from the account which follows of the hospitals forming its clinical department.

Scholarships.—The awards made each year to successful students total over £1,500. They include the following: Two Holt Fellowships, one in pathology, the other in physiology; a Robert Gee Fellowship in anatomy; two John Rankin Fellowships in anatomy; a John W. Garrett International Fellowship in bacteriology; a Johnston Colonial Fellowship in biochemistry; an Ethel Boyce Fellowship in gynaecology; and a Thelwall Thomas Fellowship in surgical pathology; one Lady Jones Fellowship in orthopaedic surgery (value of Fellowships: one at £200, three at £150, two at £120, four at £100); a University Scholarship of £50, awarded on the results of the Final M.B. (Part A) Examinations; a Ridgway Research Scholarship (£100); a Scholarship in mechanical dentistry of £20; two Lyon Jones Scholarships, of the annual value of £21 each for two years, one for the junior and the other for the senior students; the Derby Exhibition of £15; the Clinical School Exhibition of £15; the Owen T. Williams Prize; the Torr Gold Medal in anatomy; John Rankin Exhibition in practical anatomy, £25; the George Holt Medal in physiology; the Kanthack Medal in pathology; Mitchell Banks Medal in anatomy; the Robert Gee Prize of £5 5s. in children's diseases; Mary Birrell Davies Memorial Scholarship (women), £60 per annum for four years; Robert Gee Entrance Scholarship (men), value of £42 10s. per annum for four years; Dental Operating Prizes (four); Orthodontia Prizes (two); Samuels Memorial Scholarships, three at £20 each; one Thomas H. Bickerton Prize in anatomy; Dr. N. E. Robert Prize in zymotic diseases; Ash's Prize in dental surgery, value £2 2s.; Gilmour Medal; and other entrance scholarships. In addition, a number of gold and silver medals have recently been instituted in the following subjects: pharmacology, surgery, forensic medicine and toxicology, public health, medicine, obstetrics and gynaecology, orthopaedic surgery, and laryngology and otology.

Fees.—Information as to the fees for the courses of instruction provided by the schools should be sought from the Dean of the Medical Faculty.

The Clinical School.

As many as nine hospitals have combined to form the clinical school of the university, these being: The Royal Infirmary, the David Lewis Northern Hospital, the Royal Southern Hospital, the Stanley Hospital, the Royal Liverpool Children's Hospital, the Hospital for Women (with the Samaritan Hospital), the Liverpool Maternity Hospital, the Eye and Ear Infirmary, and St. Paul's Eye Hospital. Between them they provide over 1,500 beds.

MANCHESTER.

THE staff of the Medical School in this city constitutes the Medical Faculty of the Victoria University, all the arrangements for the instruction of students, both in their earlier and their later studies, being of an elaborate nature. The clinical work of the undergraduates is done chiefly in connexion with the Royal Infirmary, an institution which itself contains 614 beds, and has associated with it a large convalescent home (132 beds) and a Central Branch Hospital (54 beds). The courses in mental diseases are partly taken in the County Mental Hospitals at Prestwich and Macclesfield. Instruction in practical gynaecology and midwifery is given at the Royal Infirmary and the St. Mary's Hospitals.

Appointments.—The following are among the appointments open to past and present students of this school in connexion with its arrangements for clinical tuition: Two surgical registrars, at £150 per annum; two pathological registrars, at £100 and £50 per annum; one medical registrar, at £150 per annum; a cardiographic registrar, at £150 per annum; a surgical tutor, at £30 per annum; a director of the clinical laboratory, at £400 per annum, and two assistants, at £350 and £300; three assistant medical officers and three assistant surgical officers, each at £35 per annum; assistant surgical officers, aural department, at £35 per annum; seven anaesthetists, from £75 to £125 per annum each; one resident medical officer, one year, £200 per annum; one resident surgical officer, one year, £200 per annum; three resident medical officers for Central Branch, one at £200 and two at £100 per annum; one assistant resident surgical officer, £150 per annum; one resident medical officer at the Convalescent Hospital at Cheadle, £250 per annum; two assistant medical officers to radiological department, £150 and £105 per annum; medical officer, physio-therapeutic department, £150 per annum; assistant surgical officer, gynaecological department, £35 per annum; assistant to the dermatologist, £20 per annum; and three assistant surgical officers for Central Branch, £75 per annum; ten senior and ten junior house-surgeons and ten house-physicians, appointed during the year for periods of six months, at a salary of £50 for the first six months, and £100 for the second six months. Resident officers are appointed to the gynaecological, the eye, and the ear and throat departments every three months. Clinical clerks and surgical dressers are appointed to the various departments of the hospital every three months. Non-resident clinical assistantships for qualified medical women, tenable for six months, at an honorarium of £35.

Entrance and other Scholarships.—The following are among the scholarships obtainable by students of the school: Rogers and Seaton Scholarships in Arts (in alternate years), £40 per annum, tenable for two years. Three Hulme Scholarships, tenable for three years, of £35, one being awarded annually for proficiency in subjects of general education. Two James Gaskill Scholarships of £35, tenable for two years, one being awarded annually for proficiency in the branches of mechanics and chemistry. A Dora Muir Scholarship, £30 per annum, tenable for three years, and open to the competition of women students only. This is awarded triennially. Sir J. P. Kay-Shuttleworth Scholarship, £30 per annum, tenable for three years, awarded triennially, open to the competition of scholars from Sedbergh School, Giggleswick School, and Burnley Grammar School; subjects—mathematics, chemistry, and mechanics. Dreschfeld Memorial Scholarship, value £20, tenable for two years and awarded triennially on the result of the Entrance Examination. John Russell Medical Entrance Scholarship, awarded annually, value £45. Two Dauntesey Junior Medical Scholarships, value £50 each, tenable for one year, for candidates who have not commenced the second year of study leading to a medical qualification; subjects—zoology, botany, and chemistry. One Dauntesey Senior Medical Scholarship, £50 for one year, awarded on results of Second M.B. Examination. Two Entrance Scholarships in medicine, value 160 guineas, awarded annually for proficiency in arts or science respectively. Tom Jones Exhibition in anatomy, £25, offered annually. A Robert Platt Physiological Scholarship of £90, tenable for one year. A Leech Fellowship of £100 for original research after graduation. Graduate Prize in medicine, £5, annually. A Graduate Research Scholarship in medicine, value £70, tenable for one year, awarded annually for proficiency shown at Final M.B. Examination, open to Graduate Prizemen. A Dumville Surgical Prize, value £15, awarded annually at graduation. The Tom Jones Memorial Surgical Fellowship, value £105, tenable for one year, usually awarded annually. The Turner Medical Prizes, value 10 guineas each, awarded annually for proficiency in certain subjects of the Final M.B., Ch.B. Examination. The John Henry Agnew Prize of £30, awarded annually for proficiency in the diseases of children. The Ashby Memorial Scholarship, tenable for one year (£100), for research in the diseases of children; offered triennially. Sidney Renshaw Prize in [illegible]lly (£15). Wild Prize in pharmacolog[illegible]w Fellowship in diseases of chil[illegible] Eliza Marple Holt Post-Gradu[illegible] Women, £60 for one year, offere[illegible] 1 regulations of the Dickinson [illegible] (2) for pathology, (3) Research Scholarship in surgery, and (4) Travelling Scholarship in medicine—may be obtained from the Secretary to the Trustees. The Morrison Watson Fellowship for research in anatomy is offered annually, value £150; also the Sheridan Delepine Fellowship in preventive medicine, value £300, is offered biennially. The Sam Gamble Scholarships—the trustees are prepared to award four scholarships of not less than £40 per annum, tenable for not more than four years, to women students who have passed the First M.B. Examination; the conditions can be obtained from the Registrar. The Knight Prize of £50 for original research in the psychological factors in the causation of mental disorder—open to holders of the Diploma in Psychological Medicine or medical practitioners who have been registered in the university as candidates for that diploma.

Fees.—The composition fee for the university course in medicine is 110 guineas, payable in four instalments of 27½ guineas, but this sum does not include the fee to cover the work required for the First M.B. Examination. This is £42, payable in one sum. Hospital fees are additional, and usually amount to about 77 guineas.

A prospectus and further information about the school and scholarships may be obtained from the Registrar.

Clinical Work.—The Royal Eye Hospital, the Hospital for Diseases of the Skin, the Manchester Northern Hospital for Women and Children, the well-known Hospitals for Children at Pendlebury, and St. Mary's Hospitals for Women and Children, the Manchester Hospital for Diseases of the Ear, Monsall Fever Hospital, the Christie Cancer Hospital, the Hospital for Consumption and Diseases of the Throat and Chest, the Ancoats Hospital, and the Salford Royal Hospital, all make arrangements for the instruction of students.

SHEFFIELD.

In this city the Medical School is one of the departments of the university, being conducted and controlled by its Medical Faculty, and occupying practically the entire north wing of the quadrangle of the university buildings overlooking Weston Park. The laboratories and lecture rooms

connected with the subjects of the first and second examinations—namely, chemistry, physics, biology, anatomy, and physiology—are, both as regards structural arrangement and scientific equipment, on the most modern and complete lines.

For students of pathology and bacteriology there are laboratories replete with everything necessary for the most advanced work, and a large pathological museum, which is open daily. In addition, there is a large library and reading room. There are a number of recreation, athletic, and other societies, all under the management of an annually elected students' representative council, and large and comfortable common rooms for both men and women students. There are also two student unions—one for men and one for women students. In the university buildings there is a refectory open to all students of the school, and a university journal is published each term. The ordinary clinical work of the school is done at the Royal Infirmary and Royal Hospital, which have amalgamated for the purpose of clinical instruction, and provide over 800 beds for medical, surgical, and special cases, including diseases of the eye.

In addition, the Royal Infirmary has special departments for the treatment of diseases of the skin and ear, with beds assigned to them; whilst at the Royal Hospital there are special out-patient departments for diseases of the throat, ear, skin, orthopaedics, and mental diseases. The medical and surgical staffs attend daily, and give clinical instruction in the wards and out-patient rooms. Clinical lectures in medicine and surgery are given weekly. Instruction in the practical administration of anaesthetics is given at either institution by the anaesthetists, and the post-mortem examinations at both institutions are in charge of the Professor of Pathology, and afford ample material for study of this subject. Students are able to attend the practice of the Jessop Hospital for Diseases of Women and the Hospital for Sick Children, while special courses on fever are given at the City Fever Hospital, and on mental diseases at the South Yorkshire Mental Hospital.

Appointments.—The following appointments are open to all students who have passed their examinations in anatomy and physiology: (1) casualty dresserships, (2) surgical dresserships, (3) medical clerkships, (4) pathological clerkships, (5) ophthalmic clerkships, (6) clerk to the skin department, etc. These appointments are made for three months, commencing on the first day of October, January, April, and July.

Scholarships.—Entrance Medical Scholarship, value about £190, open to both sexes. Six Edgar Allen Scholarships of £125 a year for three years may be held by students taking the degree course in medicine. Two Town Trustees' Scholarships, each of the value of £50 a year, tenable for three years, for boys or girls under the age of 19 years who have been educated in a Sheffield secondary school for a period not less than two years immediately preceding the examination. Four Town Trustees' Scholarships, value £50 a year, for boys or girls under 19 years of age educated in any school in Sheffield, secondary or otherwise. Town Trustees' Fellowship, value £75, tenable for one year. Mechanics' Institute Fellowship, value £50 (with remission of fees), tenable for one year, and renewable for a second year. The Frederick Clifford Scholarship, value about £50, tenable for two years. Kaye Scholarship, for proficiency in anatomy and physiology. Gold and bronze medals are also awarded for proficiency in various subjects.

Fees.—Students in the Faculty taking their complete medical course in the university pay an inclusive composition fee of £33 for each of the five years. The composition fees for the dental courses are as follows: for B.D.S., first and third years, £75; second, fourth, and fifth years, £25; for L.D.S., first and second years, £75; third and fourth years, £25. The fees for special courses taken separately can be ascertained by inquiry of the Dean.

UNIVERSITY COLLEGE OF SOUTH WALES AND MONMOUTHSHIRE.

THE WELSH NATIONAL SCHOOL OF MEDICINE.

THE next session opens on October 1st. All classes are open to both men and women students. Particulars relating to the admission of students as from October 1st, 1929, can be obtained on application to the Dean of the Faculty of Medicine, or to the Secretary, Welsh National School of Medicine, Newport Road, Cardiff.

The following is a list of heads of departments: Physics, Professor H. R. Robinson; chemistry, Professor W. J. Jones; zoology, Professor W. M. Tattersall; botany, Professor R. C. McLean; anatomy, Professor C. McLaren West; physiology, Professor T. Graham Brown; materia medica and pharmacology, Dr. W. Mitchell Stevens; pathology and bacteriology, Dr. J. B. Duguid; medicine, Professor A. M. Kennedy; surgery, Professor A. W. Sheen; obstetrics and gynaecology, Professor Sir Ewen J. Maclean; preventive medicine, Professor Edgar L. Collis; tuberculosis, Professor S. Lyle Cummins.

SCOTLAND.

As will be gathered from the following paragraphs, the facilities for acquiring a medical education in Scotland are very ample, whether the student be proceeding to a university degree or to a diploma. To the descriptions of the different Scottish medical centres is in some cases added an account of hospitals which either play an official part in the education given to students as yet unqualified, or offer valuable opportunities for post-graduation work.

ABERDEEN.

THE school is conducted by the Faculty of Medicine. This comprises thirteen chairs, from which instruction is given in all the main branches of medical science—namely, botany, zoology, physics (ordinary and preparatory), chemistry (ordinary and preparatory), anatomy, physiology, materia medica, pathology, bacteriology, forensic medicine, surgery, medicine, and midwifery. Courses of instruction in public health and infectious diseases, tropical medicine, medical ethics, tuberculosis, and clinical methods are conducted by lecturers appointed by the University Court. Special opportunities for practical instruction are afforded in the laboratories and museums attached to the departments.

Clinical instruction is obtained in the Royal Infirmary (accommodating 370 patients), the Royal Mental Hospital (900 patients), the Sick Children's Hospital (132 patients), the City Fever Hospital (350 patients), the General Dispensary, Maternity, and Vaccine Institution (10,000 out-patients annually), and the Ophthalmic Institution (3,000 patients annually). Courses of practical instruction are given in diseases of children at the Sick Children's Hospital; in fevers at the City Fever Hospital; in mental diseases at the Royal Mental Hospital; in diseases of the ear, nose, and throat at the Infirmary and Dispensary; in diseases of the eye at the Infirmary and Eye Institution; in venereal diseases and diseases of the skin at the Royal Infirmary.

The degrees granted in medicine are: Doctor of Medicine (M.D.), Master of Surgery (Ch.M.), Bachelor of Medicine and Bachelor of Surgery (M.B., Ch.B.). A diploma in public health is conferred after examination on graduates in medicine of any university of the United Kingdom.

The degree of Ph.D. is also granted in this faculty.

Bursaries, scholarships, and fellowships, to the number of fifty, and of the annual value of £1,200, may be held by students of medicine in this university. They range from £8 to £150 per annum, and are tenable in most cases for two or three years. The winter session begins on October 7th, 1929; the summer session on April 21st, 1930.

Fees.—An inclusive fee of 126 guineas is payable for instruction within the university, and the fee for the degrees of M.B., Ch.B. is 33 guineas. The total cost, including hospital fees, class and matriculation fees, and degree fees, is about £242.

EDINBURGH.

THERE are two Schools of Medicine: the School of the University, and the School of Medicine of the Royal Colleges of Physicians and Surgeons of Edinburgh.

THE UNIVERSITY SCHOOL.—This school, in addition to other resources of the university, has the following means of affording practical instruction: Royal Botanic Garden, Herbarium, and Museum; zoological laboratory and museum of science and art; physical laboratory; chemical laboratories; dissecting room, bone room, and anatomical museum; physiological laboratory; medical jurisprudence laboratories; John Usher Institute of Public Health; materia medica museum and laboratory; post-mortem department of the Royal Infirmary and University Pathological and Bacteriological Laboratory; tutorial classes of practice of physic,

of clinical medicine, and clinical surgery, surgery and midwifery; and the practice of certain other hospitals.

Fees.—The sessional fee for chemistry, anatomy lectures, physiology, pathology, materia medica, surgery, medicine, and midwifery is £6 6s. each. Physics, botany, zoology, forensic medicine, and public health, £5 5s. Practical zoology, practical anatomy (summer), morbid anatomy, practical materia medica, mental diseases, practical pathology, clinical midwifery, and medical entomology and parasitology, £4 4s. Experimental physiology, diseases of tropical climates, practical botany, histology, operative surgery, clinical surgery (per term), clinical medicine (per term), and experimental pharmacology, £3 3s. Practical anatomy (winter), £6 16s. 6d. Practical chemistry, £4 14s. 6d. Regional anatomy, chemical physiology, sur[illegible] infectious diseases, £1 11s. 6d. Tuberculosis [illegible] iseases of the eye, diseases of the larynx, [illegible] of the skin, and venereal diseases, £2 12s. 6d. Advanced bacteriology, £7 17s. 6d. Clinical gynaecology and applied anatomy, £2 2s.

Scholarships.—There are many funds for the assistance of students by means of bursaries, scholarships, exhibitions, and money awards from the beginning to the end of their undergraduate career. In addition, there are funds which help those who have taken a first degree in medicine and surgery to continue at work as research students. The value of these awards, and the conditions attaching to them, are so varied that those interested should consult the prospectus of the school itself. No other university is in a better, even if as good, position to smooth the financial path of earnest students.

THE SCHOOL OF MEDICINE OF THE ROYAL COLLEGES.—This school is composed of lecturers licensed by the Royal College of Physicians and the Royal College of Surgeons, and also recognized by the university through their *licentia docendi*; for the sake of convenience they lecture in separate buildings near to the Royal Infirmary, but form a single corporate body governed by a board consisting of five members elected by the lecturers in the school. This board, with the assistance of the standing committees of the school, supervises the whole management and especially the maintenance of the efficiency and discipline of the school. The different buildings at present utilized for the purposes of lecturing are the following: (1) Surgeons' Hall, Nicolson Street; (2) New School, Bristo Street; (3) Nicolson Square; (4) Marshall Street; and other places. The teaching is similar to that of the Scottish universities, and the students receive similar certificates at the close of each session. The courses on the special subjects not included in the curriculum of the Examining Boards are also conducted by teachers specially qualified in each branch, and have for the last quarter of a century formed a special feature of the school. The fees payable for class and other instruction, and including the sums payable on admission to the examination of the Conjoint Board for the triple qualification, amount to about £180. The Calendar, giving full information regarding classes and fees, can be obtained (price 6d.) on application to the Dean of the School, Surgeons' Hall, Edinburgh.

WOMEN STUDENTS IN EDINBURGH.—Until the close of the summer session of 1916 women students intending to proceed to graduation in the University of Edinburgh, as well as those entering for the triple qualification of the Royal Colleges of Edinburgh and Glasgow, received their training in the Edinburgh School of Medicine for Women. Now women students study under the same conditions as men, and may obtain either the university degree or the diploma of the Royal Colleges. In the university systematic lectures are given to them by the professors in the ordinary classes, which are therefore mixed. In clinical medicine and clinical surgery, however, while the lectures are attended by mixed classes, the women students are restricted to the wards of one charge. The particular wards are changed every six months, each of the physicians and surgeons to the infirmary taking the women students in rotation. With few exceptions, prizes, scholarships, bursaries, and similar distinctions are open to women under the same conditions as for men. The women students also have the same privileges as in the past have been given to the men of attending a certain proportion of the extra-mural classes taught by the lecturers of the School of Medicine of the Royal Colleges. Most of the students' societies are open to women, with the exception of the University Union and the Royal Medical Society. Their place is taken by the Women Students' Union and the Women's Medical Society. There is also a Women's Athletic Club, with playing fields gifted to it by the university. The membership of the Royal College of Physicians and Fellowships of the two Royal Colleges are also open to women. Information on matters connected with women's studies may be obtained from the Adviser of Women Students, The University, Edinburgh.

GLASGOW.

THE UNIVERSITY SCHOOL FOR MEN.—The whole course of study required for graduation (M.B., Ch.B.) at the University of Glasgow can be taken here. Besides ample provision for lectures there is practical and clinical work at the hospitals, and practical courses are conducted in the laboratories of the following departments: pathology, public health, pharmacology, physiology, surgery, anatomy, chemistry, zoology, physics, and botany; the Botanic Garden and the Hunterian Museum (Pathology) are also open to students. Well-equipped new buildings have been provided for botany, zoology, practical anatomy, and operative surgery, as well as for pathology; the very large additions made a number of years ago to the chemical laboratory render it one of the most extensive in Scotland. The classrooms and laboratories for the departments of physics, physiology, pharmacology, materia medica, medical jurisprudence, and public health are also of recent erection, and are elaborately equipped. Four additional chairs of medicine, surgery, obstetrics, and pathology have been recently established, the professors being specially attached to the Royal Infirmary; and a number of university lectureships in clinical medicine, clinical surgery, venereal diseases, laryngology, dermatology, otology, psychological medicine, tuberculosis, pathological biochemistry, and electrical diagnosis and treatment have been founded there. Other chairs have been founded at the university in bacteriology, organic chemistry, physiological chemistry, applied physics, public health, and pediatrics. There are also lectureships on the surgical and medical diseases of children and on electrical diagnosis and therapeutics. The university, in short, has made great and successful efforts to extend and improve the accommodation of the medical departments, to strengthen the teaching staff, and to encourage post-graduation and research work. A diploma in public health is now also granted. Three very extensive general hospitals in the city afford exceptional opportunities for clinical instruction—namely, the Western Infirmary (600 beds), near the university, to which the Regius Professors are attached; the Royal Infirmary (688 beds); and the Victoria Infirmary (380 beds); while the Royal Mental Hospital, Gartnavel (500 beds), the Royal Hospital for Sick Children (275 beds), the Royal Maternity and Women's Hospital (114 beds), the Glasgow Eye Infirmary (100 beds), the Ophthalmic Institution (35 beds), the fever hospitals at Belvidere (680 beds) and Ruchill (540 beds), and other institutions afford facilities for the practical study of special branches. The large general hospitals of the parish council are now also available for clinical instruction in medicine and surgery. Information regarding post-graduate study will be found at page 423.

Bursaries.—Bursaries confined to the Medical Faculty amount in annual value to about £1,000, while bursaries in any faculty, amounting to about the same annual sum, may be held by students of medicine, a number of both sets being open to women. Several valuable scholarships may be held by medical students who have graduated in arts.

The following bursaries are open for competition to students entering on their first session of attendance in the Faculty of Medicine: Davidson Bursary, annual value £40, tenable for four years, for students who propose before entering the Faculty of Medicine to take the degree of B.Sc. in pure science, including in their curricula anatomy and physiology. Highland Society (Glasgow) Bursaries, annual value £25 each, tenable for five years, for students of Highland descent, open to women; two bursaries vacant each year. Logan Bursary, annual value £25, tenable for four years, open to women. Robina Eckford MacBrayne Scholarship, annual value £50, tenable for three years. Marshall Bursary, annual value £24, tenable for four years. Merchants' House Bursary, annual value £35, tenable for four years, open to women. John Oliphant Bursary, annual value £35, tenable for six years. James A. Paterson Bursaries, three each year of the annual value of £35, £25, and £15 respectively, each tenable for four years; students entering their second session are also eligible; open to women; examination in mathematics and natural philosophy.

Candidates for the aforementioned bursaries must take the university general bursary competition which is held each year in the month of June.

In addition, the following bursaries, scholarships, and prizes are open to students prosecuting their studies in the Faculty of

Medicine: Arbroath Bursary, annual value £40, tenable for four years, is awarded by the Senate, on the recommendation of the Faculty of Medicine, to the student who is of the highest merit among the candidates as shown by their class records and their performances in the First and Second Professional Examinations. Arthur Bursary, annual value £20, tenable for three years, awarded to the *woman* student who takes the highest place among the Queen Margaret College candidates at the First Professional Examination. Mary Allan Bell Bursaries (five), annual value £50 each, tenable for three or four years, for students who have gone through the curriculum in arts; special examination, tenable also in theology or law. Brisbane Bursary, annual value £50, tenable for four years; candidates must be under 22 years of age, and must have taken the degree of M.A. William Gardiner Bursary, annual value £18, tenable for two years, awarded on results of the First and Second Professional Examinations in the subjects of physiology, chemistry, and physics. Dr. Thomas Gibson Bursary, annual value £50, tenable for four years; open to medical students entering on their second winter who are preparing for service as medical missionaries. Johnston Bursaries (two), annual value £25 each, tenable for three years, for eminence in the work and examinations of the first and second years of the curriculum. Lorimer Bursaries (six), value £20 each, tenable for one year, are awarded to the best students in each of the following classes: botany, zoology, physics, chemistry, anatomy, physiology. Macfarlane Bursary, annual value £40, tenable for three years, for students who have attended the first session of their professional study in the university; examination in elementary anatomy, elementary chemistry, and botany. Mackintosh Bursary, value £31, tenable for one year, open to medical students of either sex who have attended one of the courses of lectures on insanity; examination in that subject. John Monteith Bursary, annual value £21, tenable for two years, is awarded annually to the student who gains the highest number of marks in the subjects of anatomy and physiology at the professional examinations held during the previous year. Rainy Bursary, annual value £50, tenable for two years, for students entering on their third session of medical study; awarded to the candidate whose aggregate of marks in the subjects of anatomy and physiology of the Second Professional Examination, and in chemistry, botany, and zoology of the First Professional Examination, is the highest. A. and B. Stewart Bursaries, annual value £50 each, tenable for three years, for students who have gone through the arts curriculum; there is a special examination. Walton Bursary, annual value £40, tenable for four years; the Earl of Sandwich has the right of appointing to the bursary one of two students nominated by the Senate. Weir Bursary, value £25, tenable for one year, awarded on the results of the Second and Third Professional Examinations. Barbour Scholarship in anatomy or physiology, annual value £250, tenable for two years. Joseph Coats Memorial Scholarship, value £85, tenable for one year, for research in pathology. Faulds Fellowship, annual value £250, tenable for three years, for medical research. Foulis Memorial Scholarship in pathology, value £50. Four McCunn Medical Research Scholarships, value £200 each, tenable for one year. Perman Memorial Scholarship, value £50, tenable for one year, for research in pathology. The Junior Arnott Prize of about £15; the senior Arnott Prize of £25. Three Bellahouston Gold Medals. The Brunton Memorial Prize of about £20. The Macewen Medal in surgery. The Captain H. S. Ranken V.C. Memorial Prize of £4 10s. The Straits Settlements Gold Medal. The West of Scotland R.A.M.C. Memorial Prize of about £15.

The Carnegie Trust for the Universities of Scotland is empowered to pay the whole or part of the university ordinary class fees of students of Scottish birth or extraction, under conditions given in the *University Calendar*, and summarized at page 400 of this issue. Scholarships and Fellowships are offered by the Carnegie Trust in science and medicine for post-graduation study.

Fees.—The matriculation fee for each year is £2 2s. In most cases the fee for each university class is £6 6s., but in some cases it is £4 4s. For hospital attendance at the Western Infirmary students pay £12 12s. for a perpetual ticket, or £1 11s. 6d. for a single term ticket, with an additional fee of £5 5s. for each winter and £2 12s. 6d. per term for each clinical course. The fees are the same at the Royal Infirmary. The university fees for the four professional examinations total £34 13s. For the whole curriculum the fees for matriculation, class attendance, hospital attendance, and professional examinations amount to about £250.

For further information apply to the Registrar, Glasgow University.

QUEEN MARGARET COLLEGE.—In this, the Women's Medical School of the University of Glasgow, the courses of study, degrees, regulations, fees, etc., are the same as for men. Women students have their own buildings, with classrooms, reading rooms, library, etc. They are taught in some classes apart from male students, in others together with them, but in either case have all the rights and privileges of university students. Their clinical studies are taken in the Royal Infirmary, the Western Infirmary, and the Victoria Infirmary; also *inter alia* in the Royal Hospital for Sick Children, the Glasgow Ear Hospital, the Royal Asylum, Gartnavel, Hawkhead Asylum, the Ophthalmic Institution, the City of Glasgow Fever Hospitals, Belvidere and Ruchill, and the Glasgow Royal Maternity and Women's Hospital.

Scholarships.—The Arthur Scholarship, annual value £20, tenable for three years. Open to competition by medical students of first year at the First Professional Examination in October, 1931. This scholarship is restricted to women medical students.

Full information can be obtained from the Mistress, Queen Margaret College, Glasgow.

Board for Students.—University houses of residence for women students, Queen Margaret Hall and Robertson Hall, are situated near the college. The cost of board and residence is from 32s. 6d. to 42s. a week, according to accommodation. Applications to be made to the Wardens. Another hostel near the college is South Park House, Ann Street, belonging to the Student Christian Movement, and open to women students of all colleges in Glasgow. Cost of board is from 32s. to 35s. weekly. Applications to be made to the Warden.

ST. MUNGO'S COLLEGE.—This is the Medical School of the Royal Infirmary, which is the largest general hospital in Glasgow. The Infirmary is situated in Cathedral Square, Castle Street, and has car communication with every part of the city. St. Mungo's College is in the Infirmary grounds, and affords full courses in all the subjects of the medical curriculum, and in all the medical subjects of the dental curriculum.

The Infirmary has (including the ophthalmic department) over 700 beds. There are special beds and wards for diseases of women, of the throat, nose, and ear, venereal diseases, burns, and septic cases. In the out-patient department in 1927 over 66,000 patients were treated. In addition to the large medical and surgical departments, there are departments for special diseases—namely, diseases of women, of the throat and nose, of the ear, of the eye, of the skin, and of the teeth. There is also a fully equipped electrical pavilion, with the latest and most improved apparatus for diagnosis and treatment.

Appointments.—Five house-physicians and eleven house-surgeons, who must be fully qualified, are appointed every six months, and board in the hospital free of charge. Clerks and dressers are appointed by the physicians and surgeons. As many cases of acute diseases and accidents of a varied character are received, these appointments are very valuable.

Fees.—The average class fee is £3 3s. for summer classes and £4 4s. for winter classes. The fees for all the lectures, practical classes, and hospital attendance necessary for candidates for the diplomas of the English or Scottish Colleges of Physicians and Surgeons amount to about £120. The classes are open to male and female students.

A syllabus of classes can be obtained on application to the Secretary to the Medical Faculty, St. Mungo's College, 86, Castle Street.

THE ANDERSON COLLEGE OF MEDICINE.—This school provides education in all subjects of the curriculum for both medical and dental students. The school buildings are situated in Dumbarton Road, immediately to the west of the University and Western Infirmary. The hospital practice and clinical lectures are provided in the Western or Royal Infirmary; pathology in the Western or Royal Infirmary; vaccination and dispensary practice in the Western or Royal Infirmary Dispensary. These classes are recognized by all the licensing corporations in the United Kingdom, also by the Universities of London, Durham, Glasgow, and Edinburgh (the latter two under certain conditions stated in the school Calendar). The courses (lectures and laboratory) in public health are recognized by the Scottish Licensing Board, the Universities of Oxford, Cambridge, and London, and the London and Irish Colleges.

Fees.—The fees for the lectures and practical work required by ordinary students range between 2 and 6 guineas a session. In the Public Health Department the fee for a six months' course is £14 14s. The Carnegie Trust pays the fees of students at Anderson College on conditions regarding which particulars may be obtained from the Secretary, Carnegie Trust Offices, Edinburgh.

A Calendar will be sent on receipt of a postcard by the Secretary to the Medical Faculty, the Anderson College of Medicine, Glasgow, W., who will forward any further information which may be desired.

The Royal Samaritan Hospital for Women, Glasgow, with 160 beds, offers facilities for clinical instruction in the diseases peculiar to women. A university lectureship, the

Royal Samaritan Lectureship in gynaecology, is associated with the hospital. The lecturer is Dr. David Shannon. Particulars may be obtained from Mr. T. Mason Macquaker, M.A., Secretary, 149, St. Vincent Street, Glasgow.

St. Andrews and Dundee.

The medical departments in these two teaching centres cater specially for students proceeding to the degrees of the University of St. Andrews, but admit other students as well. In the former city the United College provides education in all subjects for the first two years. In Dundee, University College provides for the needs of students from the beginning to the end of the five years' curriculum. Its buildings are modern, and contain fully equipped laboratories. The clinical work of the school is facilitated by various institutions. The class fees are from £6 6s. to £5 12s. 6d. for systematic classes, and from £4 14s. 6d. to £4 4s. for practical classes. The hospital ticket is £1 8s. for three months, £4 4s. a year, or perpetual, £13 6s. 8d. in one sum. The inclusive or composition fee for the curriculum is £182. In connexion with both institutions there are bursaries and scholarships of considerable value, which are awarded after competitive examination. Information as to these can be obtained from the Secretary of the University of St. Andrews. Information regarding the clinical facilities may be obtained from the Dean of the Medical Faculty, Medical School, Dundee.

Clinical Work.

Good opportunities for clinical work are afforded by the Dundee Royal Infirmary, the instruction given thereat being recognized for purposes of graduation by all the Scottish universities, the University of Cambridge, the University of London, the National University of Ireland, and by the Royal Colleges of England and Scotland.

IRELAND.

There is a choice of six schools for those pursuing their medical studies in Ireland. For clinical instruction the choice is equally wide and varied, though the hospitals themselves are comparatively small. Some account of the schools follows.

Dublin.

School of Physic.

This school is in Trinity College, Dublin, and is carried on under the joint auspices of the University of Dublin and of the Royal College of Physicians of Ireland, the King's professors of institutes of medicine (physiology), practice of medicine, materia medica, and midwifery being appointed by the latter. Clinical instruction is given at Sir Patrick Dun's Hospital, and some twelve other metropolitan hospitals and asylums are recognized by the Board of Trinity College. The courses of instruction are open to all medical students, whether they belong to the university or not.

The Schools of Surgery.

These are schools carried on in Dublin under the supervision and control of the Council of the Royal College of Surgeons. They are formed of the college's own school, combined with two famous old medical schools—Carmichael and Ledwich; they are attached to the college by charter. The buildings contain spacious dissecting rooms, special pathological, bacteriological, public health, chemical, and pharmaceutical laboratories. Advantage can be taken of the lectures and instruction afforded by students otherwise unconnected with the college.

Prizes.—Among the prizes annually awarded are: The Barker Anatomical Prize (£26 5s.); the Carmichael Scholarship (£15); the Mayne Scholarship (£8); the Gold Medal in surgery; the Stoney Memorial Gold Medal in anatomy; the H. Macnaughton Jones Gold Medal for midwifery and gynaecology; the Captain Massey Miles Memorial Prize; class prizes, accompanied by silver medals, will also be given in each subject. At intervals a prize of £150 is awarded, called the R. Dancer Purefoy Memorial.

A prospectus can be obtained post free on application to the Registrar, Royal College of Surgeons, Dublin.

University College, Dublin.

This is one of the constituent colleges of the National University of Ireland. The arrangements for the teaching of medical students from beginning to end of the curriculum are adequate. Applications for information may be addressed to the Secretary and Bursar, University College, Dublin.

Clinical Teaching in Dublin.

There are numerous well-arranged hospitals in and around the city, and almost all of these are recognized for teaching purposes by the Conjoint Board of Ireland, the University of Dublin, the National University of Ireland, and by like bodies elsewhere in the British Isles. Among them are the Mater Misericordiae Hospital, with 345 beds; Dr. Steevens's Hospital at Kingsbridge, with 150; Meath Hospital and County Dublin Infirmary, with 160; Mercer's Hospital, with 120; the Royal City of Dublin Hospital, with 124; the Adelaide Hospital, with 160; the Royal Victoria Eye and Ear Hospital, with 100 beds; Sir Patrick Dun's Hospital, which has a direct connexion with the School of Physic, and the combined institutions formed by the Hardwicke Fever Hospital, the Richmond Surgical Hospital, and the Whitworth Medical Hospital, with an aggregate of 330 beds.

As for the famous Dublin medical institution known as the Rotunda Hospital, this practically consists of two distinct hospitals, and is believed to be the largest combined maternity and gynaecological hospital in the British Isles. It receives nearly 3,000 patients every year, and, apart from ordinary out-patient work of a gynaecological order, annually attends some 2,000 women in their own homes during their confinement. There are ante-natal and paediatric departments as well as a thoroughly equipped pathological laboratory, and *x*-ray apparatus. It possesses residential quarters for students, and, taken as a whole, offers exceptional opportunities for study both to ordinary students and to medical graduates of any nationality.

Two other important obstetric and gynaecological hospitals in Dublin are the Coombe Lying-in Hospital and the National Maternity Hospital. During the year ending December 31st, 1927, the number of cases dealt with in the Coombe Lying-in Hospital were as follows: intern maternity department, total admissions 1,042; intern maternity department, total deliveries 950; extern maternity department, total cases treated 1,494; gynaecological department, number of operations 462.

At the National Maternity Hospital, Holles Street, Dublin, during the year ending March 31st, 1929, there were admitted to the maternity department 997 patients, and to the gynaecological department 394; 811 calls were received in the extern obstetrical service; 961 patients were delivered in the hospital and 631 in their homes; 383 operations were performed.

The practice of these hospitals is attended by large numbers of students, post-graduates, and nurses.

Belfast.

The Medical School is part of the Faculty of Medicine of Queen's University, Belfast, and provides a complete medical curriculum for all purposes. The laboratories in connexion with the departments of bacteriology, biochemistry, biology, chemistry, physiology, pathology, anatomy, physics, and materia medica are all excellent, and there is a students' union which gives students the advantages of dining rooms, reading rooms, a library, and various recreation rooms. Women are eligible as students. Clinical instruction is given at the Royal Victoria Hospital, which was rebuilt a few years ago and has 300 beds, and the Mater Infirmorum Hospital, which has 150 beds. Other hospitals open to the students of the university are: the Maternity Hospital, the Ulster Hospital for Women and Children, the Hospital for Sick Children, the Ophthalmic Hospital; the Benn Ulster Eye, Ear and Throat Hospital; the Union Infirmary and Fever Hospital; the Fever Hospital, Purdysburn; the District Lunatic Asylum, the Samaritan Hospital, Forster Green Hospital for Diseases of the Chest, and the Belfast Hospital for Skin Diseases.

Scholarships.—(1) Eight, of the value of £40 each, are assigned as Entrance Scholarships in the Faculties of Arts, Science, and Medicine, tenable for one year; (2) fourteen Professional Scholarships, value from £15 to £40 each; (3) one Hutchinson Stewart Scholarship, £12, in mental diseases; (4) one Mackay Wilson Travelling Scholarship, £100, awarded triennially; (5) Isabella Tod Memorial Scholarship, tenable for three years, awarded triennially to a woman student; (6) Magrath Clinical Scholarship, awarded annually, value about £112; (7) two Musgrave Studentships of £200 in physiology and pathology. There is also a post-graduate research fund, open to all graduates of not more than three years' standing. Gold medals are awarded at the M.D. examination.

Fees.—The cost of the curriculum intended for students proceeding to the degrees of the Queen's University of Belfast is, approximately, £200. This includes examination fees and a perpetual ticket for attendance at the Royal Victoria Hospital or the Mater Infirmorum Hospital, and fees for the special hospitals. The course for the Conjoint Board costs about the same amount.

The Regulations of the Medical Faculty, containing full information, can be obtained on application to the Secretary, Queen's University, Belfast, price 4d.

University College, Cork.

This institution, formerly known as Queen's College, Cork, is one of the constituent colleges of the National University. It holds examinations for all the faculties of that university, in addition to continuing the work which it has hitherto performed—namely, that of providing education adapted to the needs of medical students at all stages of their career. Its first aim is to fit students for the degrees of the National University, but students proceeding for the examinations of the Conjoint Board of England, Scotland, or Ireland, the Society of Apothecaries of London, or the Apothecaries' Hall of Ireland, or London University, can arrange the courses of lectures which they attend, and the order in which they attend them, to meet the requirements of those bodies. Certificates of attendance at the college courses are also accepted by the University of Cambridge. Clinical instruction is given at the North and South Infirmaries (each 100 beds) and at the Cork Union Hospital (1,200 beds). Students can also attend the Mercy Hospital (130 beds), the County and City of Cork Lying-in Hospital, the Hospital for Diseases of Women and Children, the Fever Hospital, the Ophthalmic and Aural Hospital, and the Eglinton Lunatic Asylum. The session extends from October to June.

There is a Dental School in which the degree of Bachelor of Dental Surgery of the National University of Ireland can be obtained. There is a large well-equipped dental hospital in connexion with the school.

Scholarships.—About £3,000 is available annually for scholarships in the college. Particulars as to each of them can be obtained on application to the Registrar.

Fees.—The fees for the lectures and hospital attendances required by the National University of Ireland course, including examination fees, come to about £170.

Further information can be found in the Calendar or obtained on application to the Registrar.

University College, Galway.

This institution is one of the constituent colleges of the National University of Ireland, and includes Faculties of Art, Science, Law, Celtic, Engineering, Commerce, and Medicine. The college buildings are well lighted and well ventilated, and contain dissecting rooms, an anatomical theatre, and laboratories for the study of physiology, chemistry, physics, and other departments of medical science. For pathology and chemistry new laboratories are now provided. It has good grounds surrounding it, and there are many arrangements, such as a library, a college union, and an athletic union, for the benefit of those belonging to the Medical Faculty, as well as for students in other departments of the college. The clinical teaching, which is recognized as qualifying not only for the degrees of the National University, but for those of the London University and the diplomas of the various colleges in the three kingdoms, is carried on at the Galway Central Hospital and the Galway Tuberculosis Hospital. The Galway Central Hospital is a general hospital, and at the two hospitals students have ample opportunities of studying zymotic and chronic diseases. The Central Hospital has a special ward for diseases of children. Each year the governing body offers about £2,500, and the County Councils of Connaught offer about £3,500, in scholarships. These scholarships are tenable in any faculty. Additional information regarding these scholarships can be obtained on application to the Registrar, and to the Secretaries of the Connaught County Councils.

CLINICAL HOSPITALS IN ENGLAND.

Many hospitals in Great Britain and Ireland, though not connected with any medical school, open their doors either to those who have yet to be qualified, to those who are doing post-graduation work, or to both. The facilities they offer for gaining practical clinical experience are very great, and should not be overlooked. Their honorary staffs commonly make a point of giving such instruction as opportunity offers, and at those situated in the larger towns there are often appointments as clinical assistants to be obtained. In addition, they all have to offer, at shorter or longer intervals, appointments for resident medical officers, house-physicians, and house-surgeons. These are usually paid offices, which may be held for periods varying from six months to a year, or even longer. Some of those situated in the great medical centres in the provinces, and in Scotland and Ireland, have already been mentioned in speaking of the medical schools in these localities; but it should be added that there are many other provincial hospitals where admirable work is done, and at which much valuable experience can be gained by both senior and junior students, and by those already qualified. Cases in point are the Royal Infirmary, Bradford; the Royal Sussex County Hospital, Brighton; the Royal United Hospital, Bath; the Kent and Canterbury Hospital; the Derbyshire Royal Infirmary; South Devon and East Cornwall Hospital, Plymouth; the Royal Albert Hospital and Eye Hospital, Devonport; the Royal Devon and Exeter Hospital; the West of England Eye Infirmary, Exeter; the Gloucestershire Royal Infirmary and Eye Institution; the Royal Infirmary, Leicester; the County Hospital, Lincoln; the General Hospital, Northampton; the Norfolk and Norwich Hospital; the General Hospital, Nottingham; the Royal Portsmouth Hospital; the Royal Berks Hospital, Reading; the Royal South Hants and Southampton Hospital; the Staffordshire General Infirmary, Stafford; the North Staffordshire Infirmary at Hartshill; the Royal Hants County Hospital, Winchester; the Wolverhampton and Staffordshire General Hospital; the County Hospital, York; and the Coventry and Warwickshire Hospital.

London Clinical Hospitals.

As for the hospitals in the metropolis, so many of these take a share in the giving of clinical instruction that it is worth while to classify them.

Children's Hospitals.—There are at least seven of these, the leader among them being the Hospital for Sick Children, Great Ormond Street, which has 268 beds. There are also the East London Hospital for Children, Shadwell, with 136; the Queen's Hospital for Children, Bethnal Green, with 134; the Victoria Hospital for Children, Chelsea, with 130; the Belgrave Hospital for Children, which has a considerable out-patient department, and in-patient accommodation for 74 children; the Paddington Green Children's Hospital; and the Evelina Hospital for Sick Children, Southwark Bridge Road, with 76 beds. The largest and the oldest of the hospitals for both women and children is the Royal Waterloo Hospital for Children and Women, Waterloo Road, S.E.1.

Hospitals for Women.—Queen Charlotte's Maternity Hospital, Marylebone Road, with 75 beds and a residential college for medical students and [illegible] the teaching of midwifery. The City [illegible] al, City Road, with 71 beds, also adm[illegible] aduates to its practice. The Samarit[illegible] ylebone Road, admits qualified pract[illegible] to both the in-patient and out-patient departments; demonstrations are given daily in both departments, the fees—payable in advance—being £3 3s. for three months; full particulars may be obtained from the secretary. In addition may be mentioned the Hospital for Women, Soho Square, whose teaching is confined to post-graduates in limited numbers; the Chelsea Hospital for Women, Arthur Street, Chelsea; and the Elizabeth Garrett Anderson Hospital for Women in Euston Road, the latter being in the nature of a general hospital so far as concerns the class of case treated.

Eye Hospitals.—The largest of these is the Royal London Ophthalmic Hospital (Moorfields), City Road, E.C.1, 138 beds; 2,438 in-patients, 51,841 out-patients in 1927. At this hospital two complete courses of instruction are given during the year—October to February, and March to July—comprising the following subjects: (1) anatomy (including histology and embryology), (2) physiology, (3) optics (including physiological optics), (4) refraction

classes, (5) methods of examination and use of the ophthalmoscope, (6) pathology and bacteriology, (7) ophthalmic medicine and surgery, (8) ophthalmoscopic conditions, (9) operative surgery, (10) practical pathology, (11) practical bacteriology, (12) radiology, (13) physiotherapy (including ultra-violet light, diathermy, and ionization), (14) slit-lamp microscopy. A fee of 31 guineas will admit the holder once to all the lectures and classes, except those on physiotherapy and slit-lamp microscopy. The fee for a perpetual ticket to attend the practice of the hospital is £5 5s.; for three or six months, £3 3s.; for two months, £2 2s.; for one month, £1 1s. Registered medical practitioners and medical students are eligible, under certain conditions, for the posts of chief clinical assistant, clinical assistant, and junior assistant. There are also a number of salaried posts, an annual Clinical Research Scholarship of £50, and a biennial Gifford Edmonds Prize of £100. Clinical work begins each morning at 9 and operations at 10 o'clock. The course of instruction is specially adapted to meet the requirements of those reading for the D.O.M.S. and similar diplomas and degrees in ophthalmology. Further particulars may be obtained from the Dean of the Medical School. Other eye hospitals are the Royal Westminster Ophthalmic Hospital, lately rebuilt on a new site in Broad Street, High Holborn, and containing 84 beds; the Royal Eye Hospital, Southwark, and the Central London Ophthalmic Hospital, Judd Street, W.C.1, each with about 40 beds; and the Western Ophthalmic Hospital with 18 beds.

Fever Hospitals.—The Metropolitan Asylums Board has under its control a good many institutions in and around London for the treatment of the more serious zymotic disorders; it makes special arrangements for the instruction of students in this subject, and grants certificates at the end of the courses. Detailed information should be sought from the Clerk to the Board, Victoria Embankment, E.C.4.

Chest Hospitals.—The largest of these is the Brompton Hospital for Consumption, which has 333 beds and a large sanatorium at Frimley with 150 beds. There is also the City of London Hospital for Diseases of the Chest, Victoria Park, with 185 beds, and the Royal Hospital for Diseases of the Chest, City Road, with 85 beds, now amalgamated with the Royal Northern Hospital, Holloway Road.

Nose, Throat, and Ear Hospitals.—The institutions which confine their work to disorders of the throat, nose, and ear all make special arrangements for the benefit of senior and post-graduate students. They are the Metropolitan Ear, Nose, and Throat Hospital, Fitzroy Square; the Royal Ear Hospital, Dean Street; the Central London Throat, Nose, and Ear Hospital, Gray's Inn Road; and the Hospital for Diseases of the Throat, Golden Square—the last, which possesses 75 beds, being the largest of the four institutions.

Miscellaneous Special Hospitals.—Among these are the Bethlem Royal Hospital, St. George's Road, S.E.1, which (like the Maudsley Hospital) confines its work to the treatment of mental diseases, and includes a department for nervous and early mental disorders; the Royal National Orthopaedic Hospital, Great Portland Street; St. Peter's Hospital for Stone and Urinary Diseases, Henrietta Street, Covent Garden; St. Mark's Hospital, City Road, which devotes itself to the treatment of diseases of the rectum, including cancer and fistula; the National Hospital for Diseases of the Heart in Westmoreland Street, W.1; St. John's Hospital for Diseases of the Skin in Leicester Square; the Hospital for Diseases of the Skin, Stamford Street, Blackfriars; the National Hospital, Queen Square, W.C.1, an institution possessing 200 beds for neurological cases and a world-wide reputation; and the West End Hospital for Nervous Diseases, 73, Welbeck Street, W.1.

Detailed information as to the teaching arrangements of all these institutions may be obtained on application to their secretaries.

WOMEN IN MEDICINE.

The regulations of the General Medical Council and of the various universities and colleges set out in previous sections apply to women as to men.

Examinations.

Women are admitted to all the medical examinations of the following qualifying bodies: all the universities of Great Britain and Ireland; the Royal College of Physicians of London; the Royal College of Surgeons of England; the Society of Apothecaries of London, and the Conjoint Boards in Scotland and in Ireland. In addition, women are eligible for election as Fellows of the Royal College of Physicians of London and the Royal College of Physicians of Edinburgh.

Medical Education.

The general tendency during the years since the war has been to admit women to train in medicine at the same schools and under very much the same conditions as men. In this country at the present time co-education is the general rule. The schools of the London hospitals have, however, so far shown themselves more conservative in this respect than the rest of the country.

In England the colleges connected with the universities of Birmingham, Bristol, Cardiff, Leeds, Liverpool, Manchester, Newcastle, and Sheffield admit women students as well as men, whilst in Scotland the universities of Aberdeen, St. Andrews, Edinburgh, and Glasgow also admit women. In Ireland all universities and colleges are open to them.

In London several of the old-established hospitals opened their doors to women students during the war, but have now reverted to their previous status of schools for men only. This is an unsatisfactory state of affairs, which it appears can only be temporary, no unsatisfactory results of co-education having been brought forward by any of the schools so closing their doors to women.

At the present time the only co-education hospital in London is that of University College—the number of women entrants is restricted to twelve a year, but these twelve (making between thirty-six and forty-eight training at any one time for the three to four years' clinical course) are given excellent opportunities whilst students, and also, in fair proportion, are given opportunities of post-graduate experience as *residents*—house-surgeons, house-physicians, and obstetrical assistants.

Number of Women Medical Students.

Returns made to the University Grants Committee at the end of 1928 showed that the total number of full-time women medical students attending university institutions in England, Scotland, and Wales during the past five years were:

	1923-24.	1924-25.	1925-26.	1926-27.	1927-28.
England	1,375	1,197	1,059	930	862
Wales	35	32	30	32	30
Scotland	610	431	313	274	254
Total	2,020	1,660	1,402	1,236	1,146

The London (Royal Free Hospital) School of Medicine for Women.

The London (Royal Free Hospital) School was started for the training of women in medicine in the days before there were any co-education facilities for them, and it still remains by far the largest school for women. In addition to the clinical work at the Royal Free Hospital, arrangements are made for students of the school to obtain clinical instruction at the National Hospital for Nervous Diseases, Queen Square; the Royal London Ophthalmic Hospital, Moorfields; the Great Ormond Street Hospital for Children; the Elizabeth Garrett Anderson Hospital; the South London Hospital for Women; and the Cancer Hospital. Its importance for women in medicine can hardly be overestimated, not merely because it was the pioneer which made the way possible, but also because it is still the only general hospital in Britain which offers all its post-graduate appointments, higher and lower, to open competition by women as well as men, thus giving unique opportunity of gaining experience. Not only are all the resident appointments at the Royal Free Hospital, of which there are twenty-seven yearly, eligible for women, but, in addition, higher posts may be obtained in all the various branches of a general hospital, from those of registrar and anaesthetist to those of visiting physician or surgeon and those in charge of special departments. There is a special unit in gynaecology under a woman professor, and entirely staffed by medical women. This policy has so far not been fully adopted in its entirety by any other hospital, and it may be of interest to note in this connexion that the Royal Free Hospital has many women on its general committee and weekly board of management.

Openings for Medical Women.

There are at the present time the names of over three thousand medical women on the *Medical Register*. Owing to the artificially stimulated demand for women to enter medicine during the latter part of the war, there was, for a short time, a greater number of women qualifying

than could be readily absorbed in the various branches of medical work. This was, however, purely transitory, and the demand now is approximately as great as the supply. There is an increasing demand by the public for the services of women doctors in all branches of medicine, and statistics show that the number of those who make good is as high, if not somewhat higher, than that of their men colleagues.

Openings at Home.

House Appointments.—The valuable post-graduate experience obtained in these posts is eagerly sought by both men and women, and it is therefore only to be expected that the increase in the number available to women should be gradual. In addition to the Royal Free Hospital, where by far the greatest number are available, the co-education hospitals show an increasing tendency to admit their women graduates in due proportion to these posts, and in addition women are appointed as residents in many of the non-teaching general hospitals, hospitals for women and children, sanatoriums, infirmaries, fever hospitals, and asylums.

General Practice.—There are good openings as assistants or, better still, as assistants with a view to admission as partners in general practice. Medical women also do very well when starting in new districts; and there is considerable scope for them in midwifery work.

Specialist and Consulting Practice.—This naturally only becomes possible as hospitals admit women as physicians on their honorary staffs; in this respect the Elizabeth Garrett Anderson Hospital and the South London Hospital for Women have rendered invaluable service to women in medicine. As has been mentioned, the Royal Free Hospital also has a considerable number of women on the staff, whilst in the provinces women are making satisfactory progress in this direction. To mention a few—at Bath, Bristol, Edinburgh, Glasgow, Hereford, Liverpool, and Manchester—there are women on the honorary visiting staffs of general hospitals and special hospitals as general physicians, surgeons, gynaecologists, orthopaedic surgeons, children's specialists, and infants' specialists. It is interesting to note that there are already women in successful practice as consulting physicians, surgeons, gynaecologists, ophthalmologists, ear, nose, and throat specialists, urologists, dermatologists, anaesthetists, tuberculosis specialists, venereal disease specialists, x-ray and light treatment specialists, psychologists, specialists in orthopaedic work, children's diseases, bacteriology and pathology, and spa treatment, etc. Research work also provides interesting openings, as, for example, in dealing with the special problems concerning cancer, nutrition, puerperal morbidity and mortality, statistical work, etc., and for some of these research scholarships and grants are available.

Teaching Posts.—Women hold professorships and lectureships at various universities.

Industrial Medicine.—In this branch there is much interesting work available, and it is undergoing considerable development at the present time. Several women already hold such posts.

Administrative Work.—A certain number of these important posts are admirably filled by medical women. The chief medical officer for maternity and child welfare is a medical woman, and has a staff of medical women to assist her.

The Public Health Service.—This service provides numerous openings for medical women. It has many departments, and its rapid growth in recent years has provided much interesting work in preventive medicine. For maternity and child welfare work women have been found to be peculiarly suited; but, by a curious economic limitation, married women, who would appear to be the most suitable of all, are, by many public authorities, excluded from service. This exclusion not only prevents married women from taking part in this work, but also prevents many of the best women from specializing in this branch of medicine, as it is obviously uneconomic to specialize in a branch of public service from which one may be excluded in a few years.

Medical Inspection, etc.—Under the Board of Education there are women serving as medical advisers and school medical inspectors. The London County Council and other important councils in the country have medical women on their permanent medical staffs, both in the senior and junior grades. The London County Council has two of its senior medical women appointed to serve as district medical inspectors. In addition, they have a large number of women medical inspectors of school children, and also women are serving as experts in the departments dealing with mental deficiency, tuberculosis, and venereal disease. Some medical women also serve as examiners of the candidates entering the public services, as, for example, the civil service. The services of medical women are extensively enlisted by public authorities in dealing with employees of their own sex. In several instances women serve as assistant medical officers to prisons, and in one instance at least a woman has recently been appointed as the medical officer for the police women of a large city. The services of medical women are also enlisted as lecturers and examiners on first aid, home nursing, health, and infant care.

Pay and Status.

It is interesting to note that medical women, backed by the powerful assistance of the British Medical Association, have been on the whole successful in resisting the attempt to accept a lower salary for the same work as their men colleagues, thereby not only greatly benefiting themselves, but also maintaining the standard for the whole profession. They realize that ever since the admission of women to the medical profession exactly the same sacrifices for principle have been made by their predecessors as are now demanded from them. With the inauguration of the School Medical Service in 1908, and later when maternity and child welfare posts were created, persistent efforts were made by local authorities to pay their assistant medical officers below the minimum arranged by the representatives of the public authorities and the British Medical Association, and to secure women at a lower rate than men. With rare exceptions these efforts were a failure. Women realize as clearly as men that lowered pay invariably implies a lowered status and prestige, and that the woman who stamps herself as belonging to an inferior grade of doctor cannot complain if she is taken at her own valuation, and that a minimum always tends to become a maximum. Attempts to evade the scale and split the ranks of the profession by offering a post to a man at the agreed rate and a similar post to a woman slightly below that rate are particularly to be deprecated. Where the rule of equal pay for equal work is violated there is no limit to the extent to which women may be exploited and sweated.

Openings Abroad.

Colonial Office.—To those to whom overseas service appeals it offers the possibility of useful, interesting, and adequately paid work. At present there are only posts for women in Malaya and West Africa, and the work is almost entirely hospital and maternity and child welfare work; there have been one or two specialist appointments, such as bacteriologists, and more may follow. Women have, so far, only been appointed to the lower grade posts, but their pay is the same as that of the men in similar grades. When placed on the permanent staff they are eligible for pension.

Egypt.—Several posts are held under the education authority, chiefly in school medical inspection.

India.—See note on the Women's Medical Service for India on opposite page.

Mission Field.—Missionary societies offer employment to medical women, chiefly in India, China, and the Near East.

Public Activities.

Medical women have always shown considerable interest in medico-political affairs, and take an active part in the work of the British Medical Association, and with the various other societies dealing with medicine as it affects the community in general. With this end in view they also have a Medical Women's Federation, which enables them to voice a collective expression of opinion. This might otherwise be difficult to ascertain, as women are so widely scattered, both as regards their geographical

distribution and their varied activities. This collective opinion of medical women has been found of great assistance by the British Medical Association and other allied societies, with which it works in cordial co-operation and by whom it is frequently approached, both for information and also as a convenient means of approaching medical women as a whole.

It may be added, with regard to contributions to medical literature, that this is a branch of work in which women are more and more taking their share, and scientific and other works are frequently published by them.

WOMEN'S MEDICAL SERVICE FOR INDIA.

This service is open to properly qualified medical women of British or Indian nationality who desire to carry on work in India. It was founded in 1913 by the Countess of Dufferin's Fund; the committee is granted a subsidy of Rs.3,70,000 by the Government of India for this purpose.

Medical women proceeding to India to join the Women's Medical Service receive a sufficient sum for a first-class passage to India. On landing they are posted to one of the larger women's hospitals to gain Indian experience and to learn the language. During this period (from six months to two years) private practice is not allowed. For a further period they are appointed to act temporarily for medical women on furlough, during which time private practice is allowed. They are then definitely appointed to the charge of hospitals.

Private practice is always allowed after the first two years, provided it does not interfere with official duties. The only exception is in administrative posts, when an allowance in lieu of practice is given. The amount obtained by practice varies according to the station, but in most cases it forms a fair addition to the salary, varying from £150 to £1,000 a year. Excellent opportunities for surgery—especially gynaecological—are found in the Women's Medical Service. The prevalence of osteomalacia in some parts of the country leads to the necessity for frequent Caesarean section, while uterine fibroids, ovarian tumours, and diseased tubes swell the number of abdominal operations. The number of large operations performed will vary with the surgical reputation of the medical woman, but in some cases it is considerable.

To those who are not keen surgeons opportunities are likely to open in the future in connexion with maternity and child welfare. The high infant mortality and the suffering of women in childbirth owing to the ignorance of the untrained hereditary midwives provide a great field for such workers. Medical women with administrative ability are also needed for the inspection of women's hospitals and other medical institutions.

Years of Service.	Rates of Pay per mensem.	Annual Salary.
1-3	Rs. 450	£360
4-6	Rs. 500	£400
7-9	Rs. 550	£440
10-12	Rs. 600	£480
13-15	Rs. 650	£520
16-18	Rs. 700	£560
19-21	Rs. 750	£600
22-24	Rs. 800	£640
Over 24	Rs. 850	£680

Furnished quarters are provided, also an overseas allowance of Rs.100 per annum, the rupee value being taken at 1s. 4d.

The above rates of pay are not so high as in the Indian Medical Service. The fact, however, that furnished quarters are provided (these are not provided in the Indian Medical Service) represents an additional Rs.150 per mensem. It must be remembered, too, that the official duties of the members of the Women's Medical Service are lighter than those of the Indian Medical Service, who, while in civil employ, in addition to work in the Civil Hospital, have charge of the medico-legal work of the district, give much gratuitous attendance, and form a reserve to be drawn on in time of war.

The cost of living in India is much higher than formerly, but even now it is possible to live more cheaply than in England for the same measure of comfort. The cost of all goods brought from Europe is very high, but the cost of country produce is much less than in Europe. Meat, poultry, milk, eggs, etc., are sold at about half the price now demanded in England. It should be possible for a medical woman (with house provided) to meet actual household expenses for about Rs.200 per mensem, leaving the remainder of her salary for dress and personal expenses. To this must be added the necessary saving to meet additional expenses for furlough and leave spent in the hills.

One month's privilege leave on full pay is granted each year. Furlough on half-pay at the rate of two months for every year of service is granted after every three years.

Study leave on furlough pay and lodging allowance at the rate of 12s. per day may be granted to the extent of twelve months in the total service.

There is a Provident Fund to which members of the service contribute 10 per cent. of their pay. The service contributes another 10 per cent., which accumulates at interest and is repaid on retirement.

Admission to the service is made by selection. Candidates in the United Kingdom should apply to the Honorary Secretary, U.K. Branch of the Countess of Dufferin's Fund, c.o. Major-General Sir Leonard Rogers, F.R.S., India Office, Whitehall, S.W.1.

POST-GRADUATE STUDY.

Notwithstanding the large and varied amount of material available, post-graduate study in London suffers from several disabilities. In the first place, teaching centres are widely scattered, and it is not easy for the student to obtain all that he requires under one roof, or even in the same district. Secondly, no definite post-graduate school exists at which the post-graduate can obtain directions for a course to suit his needs. Thirdly, there is no recognized hostel or meeting place to which the student can resort for social purposes. Each of these needs, it is true, can be obtained on a small scale at several institutions in London; but it is unlikely that what may be called the post-graduate habit will be developed until a centre for post-graduate medical education has been established.

Post-graduate students may be divided into general practitioners desirous of refresher courses to bring their general knowledge up to date; those who wish for instruction in special subjects with a view to obtaining one of the special diplomas, or of preparing for examination for promotion in one or other of the services, or—if already general practitioners—of adding some form of specialism to their work; and finally, visitors from the Dominions or abroad anxious to study the methods of British experts. The general practitioner may find a refresher course at the hospital at which he was trained, held during a vacation, and designed specially to bring his knowledge up to date; or he may approach the Fellowship of Medicine, which was amalgamated with the Post-Graduate Medical Association in 1919, and has an office generously placed at its disposal by the Royal Society of Medicine at 1, Wimpole Street, W.1. At this office a list of hospitals, special and general, to which post-graduates may resort, with or without fee, is kept, and the names of the teachers at each hospital are available. Definite courses of study at individual hospitals are also organized by the Fellowship. The West London Hospital at Hammersmith, and the Prince of Wales's General Hospital at Tottenham, have for many years had post-graduate colleges attached to them, thus overcoming, to the extent of their resources, the disabilities mentioned above. Courses of lectures and instruction are given at many special hospitals, such as the National Hospital, Queen Square, the National Orthopaedic Hospital, and certain eye, skin, and fever hospitals; and in the London School of Hygiene and Tropical Medicine, Keppel Street, Gower Street, recently opened, it will now be possible to obtain under one roof instruction in all branches of preventive medicine. The work of the school has been arranged in the following divisions, each in charge of a director and staff: public health, including a section devoted to the physiology of hygiene, whose activities will bear closely upon industrial problems; epidemiology and vital statistics; bacteriology and immunology; biochemistry, including a department for chemistry as applied to hygiene; medical zoology, embracing the departments of protozoology, helminthology, and entomology; and, finally, tropical medicine and hygiene, of which Dr. Andrew Balfour has charge, and which embraces the all-important clinical work in diseases of the tropics, for which facilities are afforded by the Hospital for Tropical Diseases in Gordon Street close by.

In the provinces the Universities of Oxford, Cambridge, Birmingham, Bristol, Liverpool, Manchester, and Sheffield have organized courses. Edinburgh receives graduates from many schools in the Dominions as well as in this country. In Glasgow and Aberdeen courses are available; and in relation with the University of St. Andrews courses are given by the staff of the James Mackenzie Institute for Clinical Research. At many of these centres the teaching is provided by way of whole-time intensive courses, by part-time courses, or by means of clinical assistantships. The Joint Tuberculosis Council has provided nomadic courses in its own special subject.

For the visitor from the Dominions or abroad very little special provision is made; but he will be able to supplement information from private sources by applying to the Fellowship of Medicine, and he will find no difficulty in obtaining entry to special hospitals, many of which provide post-graduate courses during the year. The visitor, however, will be disappointed if he hopes to find in this country anything like the cohesion and concentration in post-graduate education that is displayed in such a centre as Vienna. But in the absence of any comprehensive co-ordinating schemes, opportunities are fairly numerous and varied for the would-be student who troubles to seek out the course which he requires. Short particulars about post-graduation study in Great Britain and Ireland are given in Section VI of the *Handbook for Recently Qualified Practitioners* published by the British Medical Association (price 3s. 6d.).

Fellowship of Medicine and Post-Graduate Medical Association.

The Fellowship of Medicine has arranged regular courses in general medicine and surgery, including special departments, each lasting two weeks; the fee for each course is 3 to 5 guineas. Courses in diseases of the chest, children, ante-natal, heart, nervous system, throat, nose, and ear; dermatology; electrotherapy; gynaecology; proctology; psychological medicine; tropical medicine; urology; and venereal diseases are given from time to time at the special hospitals in association with the Fellowship of Medicine. The Fellowship "General Course" Programme contains a diary of the arrangements available for post-graduates in various general and special hospitals in London. The list for the immediate future special courses includes a two weeks' course in general medicine and surgery, from September 16th to 28th, at the Westminster Hospital; in diseases of the chest, at the Brompton Hospital, from September 9th to 14th; in diseases of infants, at the Infants Hospital, from September 9th to 21st; and in psychological medicine, at the Bethlem Royal Hospital, from September 10th to October 5th. The offices of the Fellowship are, by kind permission of the Royal Society of Medicine, at No. 1, Wimpole Street, W.1 (telephone, Mayfair 2236). The secretary is in attendance daily from 10 a.m. to 5 p.m., excepting Saturday. The annual subscription for membership of the Fellowship of Medicine and Post-Graduate Medical Association has been fixed at a minimum of 10s., which includes the subscription to the *Post-Graduate Medical Journal*.

The Fellowship arranges, during the autumn and winter sessions, a series of lectures. Special clinical demonstrations in medicine and in surgery are arranged also weekly from October onwards. Syllabuses will be sent regularly on application.

West London Post-Graduate College.

The work of this institution is carried on at the West London Hospital, the first in London to devote its clinical material solely to the instruction of qualified medical men. The college started in 1895; it is provided with lecture, reading, writing, and class rooms, and accommodation of all sorts for the convenience of post-graduate students. The work of the college is eminently suitable for men in general practice and officers in the services who wish to revive their general clinical knowledge.

As for ward work, the students accompany the senior staff on their visits to the wards at 2.30 p.m. daily, and also go round with the resident medical officers in the morning. Out-patient work begins at 2 p.m. This department is large, and affords ample facilities for post-graduates to see and examine patients. There are the usual special departments. Post-graduates are appointed to act as clinical assistants for three or six months, no charge being made. Special practical classes are held in medicine, general practical surgery, gastro-intestinal surgery, medical and surgical diseases of children, analysis of blood and urine, cystoscopy, venereal diseases, tropical diseases, retinoscopy, ophthalmic operative surgery, and, when material is available, in operative surgery. The size of the classes is limited. A special clinic for the treatment of venereal diseases (male and female) is held every evening (Saturdays included) at 5.30. Graduates are admitted to the work of the clinic free, and certificates of satisfactory attendance and work are given.

Operations take place at 2 p.m. daily, the surgeons often availing themselves of the assistance of the graduates, and in any case making arrangements so that they can readily see what is going on. The anaesthetists give instruction in the administration of anaesthetics, including spinal analgesia, on the operating days, students being allowed to administer them under supervision, while special classes are held in each session. The pathological laboratory is in charge of a pathologist, who attends every day.

Demonstrations are ordinarily given in the morning by the assistant physicians and surgeons, and by the medical and surgical registrars.

Fees.—Hospital practice, including all ordinary demonstrations and lectures, £1 1s. for one week, £4 4s. for one month, £7 7s. for two months, £9 9s. for three months, £15 15s. for six months, £23 12s. 6d. for one year, and £45 for a life ticket. Instruction in the administration of anaesthetics is given at the rate of £3 3s. a month.

The certificates of the school are recognized by the Admiralty, the War Office, the Colonial Office, the India Office, and the University of London (for higher degrees). A prospectus can be obtained on application to the Dean.

North-East London Post-Graduate College.

The headquarters of this post-graduate school are situated at the Prince of Wales's General Hospital, Tottenham, N.15, in the midst of this densely populated North London district. It contains 200 beds, and is within a few minutes' walk of South Tottenham Station on the London Midland and Scottish Railway, and Seven Sisters and Tottenham Hale Stations on the London and North-Eastern Railway. It is readily accessible by electric tram from Finsbury Park and Hackney, and from Dalston, Edmonton, and other parts of North London. The North Middlesex Hospital, Edmonton, N.18, with upwards of 1,000 beds, has, under a recent arrangement, taken part in the clinical teaching.

The college is in association with the Fellowship of Medicine and Post-Graduate Medical Association, and is recognized by the Admiralty and India Office for the purpose of study leave, and by the University of London as a place for advanced study for the M.D. and M.S. degrees; the course of practical teaching of bacteriology is approved by the University of Cambridge for its Diploma in Public Health, and there are ample arrangements for the convenience of men who are thus working, or who, being in active practice, are desirous of getting themselves into touch with modern methods. The hospital as a whole affords excellent facilities for qualified medical practitioners who wish to take part for a time in active general hospital work, or to obtain special instruction in the several branches of medicine and surgery, since it is open to them to study diseases of the eye, ear, throat, nose, skin, fevers, children's diseases, psychological medicine, dental surgery, radiography, the application of electricity in disease, and the administration of anaesthetics. Throughout the sessions, into which the year's work is divided, clinics, lectures, and demonstrations are given by members of the teaching staff. Operations are performed every afternoon of the week except Saturday. Special vacation or intensive courses are held at intervals through-

out the year, each lasting two weeks, clinical instruction being arranged for each hour of each day.

Fees.—Two guineas for three months' attendance in any one department, which may be begun at any time; a fee of 5 guineas admits to the whole practice of the hospital for a similar term (one month 2 guineas, and one year 10 guineas), and a perpetual ticket for the practice of the hospital may be obtained for 15 guineas.

The winter session will be opened about the middle of September as regards clinical teaching.

Additional information can be obtained from the Dean of the Post-Graduate College, at the Prince of Wales's Hospital.

Manchester Post-Graduate Courses.

The Faculty of Medicine of the University of Manchester has arranged courses in preparation for the diplomas in psychological medicine, in public health, bacteriology, and veterinary State medicine. There are classes also for certificates in factory and school hygiene and in venereal diseases. The Faculty of Medicine has also instituted courses to meet the requirements of graduates desiring to refresh their knowledge or to pursue further their studies in various special branches. The arrangements are in the hands of a committee consisting of certain members of the faculty, of representatives of hospitals, and of the medical officer of health for Manchester. Full particulars can be obtained from the Dean of the Medical School, the University, Manchester. Intensive courses will be given as follows during 1928–29: (*a*) in medicine and surgery, September 23rd to 27th; (*b*) in fractures, October 7th to 11th; (*c*) in oto-laryngology, March 3rd to 7th. Part-time courses in certain subjects have also been arranged, including diseases of the eye, diseases of the skin, and in bacteriology and immunity. A limited number of clinical assistantships are offered in the medical, surgical, and special departments of the Manchester Royal Infirmary, the Ancoats Hospital, and certain special hospitals for one, two, or three months, or longer.

Courses for Medical Graduates at Bristol.

The University of Bristol provides courses of post-graduate study for practitioners. Details of set courses at the Royal Infirmary and General Hospital are announced locally. In addition, practitioners may become clinical assistants in medicine, surgery, or special subjects for periods of a month or more.

Daily Post-Graduate Study.—For those who are able to devote several hours each day to hospital practice the university offers special facilities for post-graduate work. Qualified medical practitioners may be appointed as clinical assistants for a period of one or more months. They may act as assistants, if times permit, in more than one department and in any of the hospitals during their period of study. They will be entitled to the use of the clinical laboratories and medical library, and have the right to attend in all departments, including operations, post-graduate and ordinary clinical demonstrations, and post-mortem examinations.

All inquiries and applications for admission should be addressed to the Director of Post-Graduate Studies (Clinical Section), Pathological Department, University of Bristol, who can be seen on any day by appointment at the Pathological Department.

Newcastle-on-Tyne.

For the year 1929–30 the following post-graduate courses have been arranged by the College of Medicine, Newcastle-on-Tyne (University of Durham):

1. General courses in clinical medicine, surgery, and pathology at the Royal Victoria Infirmary, meeting once weekly for ten weeks. One course will be held from October to December, and one from April to June.

2. Special courses of clinical instruction meeting once weekly for ten weeks in the following subjects: gynaecology, diseases of the eye, diseases of the throat, nose, and ear, diseases of the skin, venereal diseases, neurology.

Special courses in midwifery will be held at the Princess Mary Maternity Hospital.

3. An intensive course of fourteen days' duration in the early part of the summer vacation, 1930.

4. In addition to the regular post-graduate courses practitioners may attend the ordinary medical and surgical practice of the Royal Victoria Infirmary, and also at the Princess Mary Maternity Hospital, for specified periods.

Edinburgh Post-Graduate Courses.

In connexion with the University and Royal Colleges post-graduate courses are arranged every year, from about the middle of July to about the middle of September, comprising: (*a*) a course in obstetrics, gynaecology, and diseases of children, generally held from about the middle of July; (*b*) a general practitioners' course; (*c*) a general surgical course. Courses (*b*) and (*c*) extended for four weeks from August 12th to September 7th. Similar courses are held each year.

The course in obstetrics, gynaecology, and diseases of children comprises instruction in clinical midwifery and clinical gynaecology, obstetrics and gynaecological pathology, diseases of children, child welfare, and ante-natal clinics, etc.

The general practitioners' course includes lecture-demonstrations, and, where possible, practical instruction on medical anatomy, medical sideroom work, examination of the blood, *x*-ray and electrical therapy, morbid anatomy, and post-mortem examination; clinical instruction in medicine, surgery, gynaecology, diseases of children, diseases of the skin, and infectious diseases; and special instruction in the diseases and methods of examination of the nervous, circulatory respiratory, alimentary, and renal systems, and in diseases of the ductless glands. The general surgical course includes lecture-demonstrations on surgical anatomy, surgical pathology, and surgical *x*-ray diagnosis; clinical instruction in surgery at the Royal Infirmary and Royal Hospital for Sick Children; clinical instruction in venereal diseases; surgical out-patients, surgical and gynaecological operations, and special instruction in abdominal and genito-urinary and other branches of surgery.

A series of special lectures, open to all graduates, is delivered on subjects of general medical and surgical interest, including recent advances in treatment. Among the special courses also arranged are: examination of the blood, vaccine therapy, medical chemistry, diseases of the ear, nose, and throat, radiology, ophthalmoscopy, and venereal diseases.

Particulars regarding the courses, dates of commencing, fees, etc., may be had on application to the Honorary Secretary, Post-Graduate Courses in Medicine, University New Buildings, Edinburgh.

Post-Graduate Medical Teaching in Glasgow.

Organized post-graduate medical teaching is available in Glasgow under the auspices of the Post-Graduate Medical Association. This association represents practically all the teaching institutions in Glasgow and the various teachers giving post-graduate instruction, and its business is managed by a board elected periodically by them. The chairman of the board is Principal Sir Donald MacAlister, Bt. During the winter months special courses in various subjects are conducted, and from November till May there is a series of weekly demonstrations specially designed for local practitioners. Clinical courses are carried out during the summer months, and arrangements have also been made whereby a limited number of graduates may become attached to wards or out-patient departments nominally as clinical assistants for definite periods throughout the year. As such they work under the direct supervision of the physician or surgeon in charge, and carry out such detailed investigations as directed.

A general medical and surgical course is held each year during the last two weeks of August and the first two weeks of September, which is arranged to include most of the subjects of interest to the general practitioner. This year the course is being conducted from August 19th to September 13th. The forenoons are occupied with general medicine and surgical diagnosis and minor surgery, in the Victoria Infirmary and in the Western Infirmary. In the afternoons special subjects are dealt with in the special hospitals and in the special departments of the general hospitals, two subjects being considered most afternoons.

Further information may be had on application to Dr. James Carslaw, Secretary, Post-Graduate Medical Association, 9, Woodside Terrace, Glasgow, C.3.

AUSTRALIAN AND NEW ZEALAND MEDICAL ASSOCIATION.

The Australian and New Zealand Medical Association gives information and advice to medical visitors from the Commonwealth and Dominions with regard especially to attendance at special clinics, post-graduate work, and facilities for preparing for examinations such as the M.R.C.P., F.R.C.S., etc., and also as to house appointments and clinical assistantships in London and the provinces. Information will also be given as to lodgings, sports, and social opportunities. Two dinners are held annually. All medical graduates or undergraduates born in Australia or New Zealand and resident in or visiting England are eligible to become members. The fee is one payment of 5s. Further information can be obtained from the joint honorary secretaries, Mr. E. T. C. Milligan, F.R.C.S., 86, Harley Street, W., and Mr. Philip J. Jory, F.R.C.S., 26, Queen Anne Street, W.

TROPICAL MEDICINE.

THERE are large and important schools of Tropical Medicine in London and Liverpool, and several universities and other examining bodies have instituted diplomas or degrees in the subject. The Colonial Office now expects all nominees for the Colonial Medical Service to pass through one or other of the two schools mentioned before their appointments are confirmed, and commercial firms engaged in tropical enterprise commonly demand from medical applicants for employment corresponding evidence of special knowledge. Information with regard to these schools and diplomas and degrees is given in the paragraphs printed below. Further particulars will be found in the *Guide to Regulations, Courses, and Qualifications in Public Health and Tropical Medicine and Hygiene*, compiled by Dr. Andrew Balfour, Director of the London School of Hygiene and Tropical Medicine, and published by the British Medical Association (price 3s.). This useful handbook contains, among other matter, a list of the teaching centres and examining bodies, with the qualifications obtainable from them. The University of London alone gives a degree (M.D.) in Tropical Medicine, and this, being an "internal degree," can only be taken by students who are medical graduates of that university. Diplomas in Tropical Medicine or Hygiene are granted by the universities of Cambridge, Edinburgh, and Liverpool, and by the Conjoint Board of the Royal College of Physicians of London and the Royal College of Surgeons of England.

DIPLOMAS AND DEGREES.

LONDON UNIVERSITY.—Tropical medicine is one of the six branches in which the M.D. degree may be obtained. The regulations relating to the curriculum and examination correspond to those applying to the other branches.

THE EXAMINING BOARD IN ENGLAND.—This body grants a diploma in tropical medicine and hygiene to candidates after an examination held in the months of February and July. Candidates must present evidence of having attended, subsequently to obtaining a registrable qualification in medicine, surgery, and midwifery, (1) practical instruction in pathology, protozoology, helminthology, entomology, bacteriology, and hygiene in relation to tropical medicine, in an institution recognized for this purpose, during not less than five months; (2) the clinical practice of a hospital recognized for the study of tropical diseases during not less than five months. These conditions may be modified in the case of candidates who have had practical experience in tropical countries. The fee for admission to the examination is £9 9s. The Board also grants diplomas in public health, in psychological medicine, in ophthalmic medicine and surgery, and in laryngology and otology. Candidates must hold a medical qualification registrable in the United Kingdom, or be graduates in medicine of a recognized Indian, Colonial, or foreign university. Particulars and conditions of admission to these examinations, fees, etc., may be obtained from the Secretary of the Examining Board, Examination Hall, Queen Square, London, W.C.1.

UNIVERSITY OF LIVERPOOL.—A diploma in tropical medicine is given by this university to students who have attended the courses provided by the Liverpool School of Tropical Medicine and have passed the examination held twice yearly by the university examiners. The subjects of examination are (*a*) tropical pathology and parasitology; (*b*) entomology; (*c*) tropical medicine, including etiology, symptoms, diagnosis, and treatment of tropical diseases. Fee for the course, £21. A diploma in tropical hygiene (D.T.H.), open to the holders of the D.T.M., has recently been established. The subjects of examination are tropical hygiene (including sanitary engineering, vital statistics and epidemiology, and applied parasitology and entomology); practical sanitation, bacteriology, chemistry (including meteorology and climatology). Fee for the course, £10 10s. Further information can be obtained from the Dean of the Faculty of Medicine, University of Liverpool.

UNIVERSITY OF CAMBRIDGE.—This university grants a diploma in tropical medicine and hygiene to any person whose name has been on the *Medical Register* for not less than a year, provided that he passes the examinations of the university in this subject. Candidates for Part I are examined in the same subjects as candidates for Part I for the diploma in public health. Before admission to Part II, the subjects for which are medicine, surgery, and hygiene in their relation to tropical diseases, candidates must have passed Part I. An examination for Part I is held in April and for Part II in July. The fee for each part of the examination is 10 guineas. Application for further information should be made to Mr. J. E. Purvis, Public Health Chemical Laboratory, Medical School, Cambridge.

UNIVERSITY OF EDINBURGH.—Candidates for the diploma in tropical medicine and hygiene granted by the University of Edinburgh must be graduates in medicine and surgery of that university, or hold corresponding registrable degrees or qualifications of some other licensing body. The course of instruction extends over two terms, and may be taken either from October to March or from April to June and January to March. The examinations are written, oral, and practical, and are held at the end of the courses. Candidates are required on the first occasion of presenting themselves for examination to appear for all the subjects. Those who fail to pass the entire examination within a period of twelve months after first appearance are required to reappear for all the subjects. The university is included in the list of institutions whose courses of instruction in tropical medicine may be taken by officers on appointment to the Colonial Medical Services or during study leave. Full particulars can be obtained from the Dean of the Faculty of Medicine, Edinburgh.

SCHOOLS.

LONDON SCHOOL OF HYGIENE AND TROPICAL MEDICINE (UNIVERSITY OF LONDON).

The courses of study in all branches of the work of the school will commence in the autumn in the new premises in Keppel Street (Gower Street), the gift of the Rockefeller Foundation, which has excellent laboratories and research rooms, a fine lecture theatre and class rooms, library, and museum.

The courses of study in tropical medicine and hygiene which have hitherto been given at Endsleigh Gardens will be given in the new building. There are two courses in the year, each lasting twenty weeks, inclusive of examinations. The dates for the commencement of the next courses are September 30th, 1929, and February 3rd, 1930. The course covers the work required for the D.T.M and H. (England) and part of that required for the M.D. in tropical medicine of the University of London.

The first course of study for the diploma in public health will commence on September 30th and will extend over a period of twelve calendar months. It is arranged in compliance with the requirements of the General Medical Council, and students taking the course will be able,

should they so desire, to proceed to the new academic diploma in public health of London University. The curriculum has been planned on very practical lines, and includes, in addition to work with medical officers of health in two selected areas, a large number of visits to places of public health interest. A series of 5 o'clock lectures will be given by eminent authorities on special subjects, and these lectures will be open to members of the medical profession as well as to students of the school. The London County Council, the City of London, and various other bodies have placed their resources at the disposal of the school for teaching purposes.

The special course of study for the diploma in bacteriology covers a period of one academic year beginning in October, and special three-monthly courses commencing after the Christmas vacation will be given in epidemiology and vital statistics.

The University of Edinburgh.

A course of instruction for the diploma, comprising a primary and a second course is given during the autumn and spring terms (October to March), and includes tropical hygiene, bacteriology, entomology, and parasitology, diseases of tropical climates (systematic and clinical), tuberculosis, and venereal diseases. The primary course alone is also given during the summer term, April to June. The university is included in the list of institutions whose courses of instruction in tropical medicine may be taken by officers on appointment to the Colonial Medical Services or during study leave. Full particulars can be obtained from the Dean of the Faculty of Medicine.

Liverpool School of Tropical Medicine.

This school is affiliated with the University of Liverpool. The university now grants diplomas in tropical medicine (D.T.M.) and in tropical hygiene (D.T.H.).

Two full courses of instruction, each lasting about eleven weeks, are given every year for the D.T.M., commencing respectively September 30th (autumn term) and January 6th (Lent term); and two courses for the D.T.H., beginning on January 13th and April 23rd (summer term). The D.T.H. can only be taken by those who have obtained the D.T.M. Students who do not desire to take the diploma examinations held by the University at the end of each term are given a certificate if attendance has been satisfactory.

Fees.—(1) For the D.T.M. course, 20 guineas; for the D.T.H. course, 10 guineas. (2) For the diploma examinations, 5 guineas. An extra charge of one guinea is made for the use of a microscope if required.

The laboratories of the school adjoin the university and the tropical ward of the Royal Infirmary. The dimensions of the building are 162 feet in maximum length by 84 feet in width. In addition to the basement, in which are accommodated the photographic department and large storage rooms, there are four floors. The ground floor has: (1) lecture theatre, with accommodation for about seventy students; (2) library; (3) a spacious museum with preparation room adjoining. The first floor has twelve rooms, in which are housed the departments of tropical medicine and entomology. The second floor has the main class laboratory, 69 feet by 58 feet, excellently lighted; and three other rooms, devoted to the department of parasitology. The third floor has a large research laboratory and two research rooms. On the roof is an insectorium, a mosquito-proof house, and other accommodation.

Since its foundation the school has dispatched to the tropics thirty-two scientific expeditions, many of the workers having been taken from among its students. The work done by the staff has been published in twenty-one special memoirs—in the *Annals of Tropical Medicine and Parasitology*, issued by the school, and in numerous articles in the scientific press.

The school has also two laboratories in the tropics: the Manáos Research Laboratory in Brazil; and the Sir Alfred Lewis Jones Tropical Laboratory in Sierra Leone, which was opened on January 10th, 1922, and is staffed by the school. Further information may be obtained from the Honorary Dean, School of Tropical Medicine, Pembroke Place, Liverpool.

PSYCHOLOGICAL MEDICINE.

It cannot be impressed too strongly upon the medical student that a knowledge of mental disorder is just as essential as a knowledge of the other forms of disease which he will be called upon to treat in the routine of general practice. It must be understood that by the term "mental disorder" is not only meant those severe forms which are to be found in mental hospitals, but the term also includes mental defectives of all grades, nervous, difficult, and backward children; the mild and often unrecognized psychoses; and also the various types of psychoneurosis. Such disorders provide the general practitioner with a large proportion of his most difficult cases, and he will find a good knowledge of mental disorder invaluable in his work. Apart from general practice, the student who proposes to take up a career in the prison service or, still more importantly, the school medical service, will find a knowledge of psychological medicine an almost essential part of his equipment.

Instruction.

Though at the present time the instruction given to the student is far from adequate to supply the knowledge of mental disorder requisite for the needs of the general practitioner, the facilities for the study of psychological medicine in the general hospitals are now much greater than in former years. Thus many of the teaching hospitals have out-patient departments for the treatment of mental cases, and in some of these hospitals special lectures are given on psychopathology. These facilities need not be utilized by the student, however, and the compulsory part of the curriculum is generally confined to formal lectures and a few attendances at some mental hospital. Here the student is apt to see mainly the terminal states of mental disease, and he is also apt to gain the impression that mental disorder is necessarily related to segregation and custody. We would therefore impress upon him the importance of attending the out-patient department for mental disorders, where he will be able to observe the mild and early cases such as he will hereafter meet with in general practice.

A scheme is now in actual operation at the Middlesex Hospital in which a small number of mental cases are treated in the hospital as in-patients. This is an important move from the teaching point of view, because the student will gain true insight into the relation between mental disorder and medicine as a whole, and he will realize that it is a form of illness to be studied with other diseases and to be treated along similar lines.

In London post-graduate courses of instruction of a comprehensive kind are given at the Maudsley Hospital and at Bethlem Hospital; and at the National Hospital, Queen Square, courses are arranged to meet the requirements for the diploma in psychological medicine in regard to nervous diseases. Courses in mental deficiency are arranged by the University of London. There are also post-graduate courses at the Universities of Glasgow, Cambridge, Edinburgh, Birmingham, Leeds, Manchester, Durham, and elsewhere.

Diplomas.

Those who are taking up psychiatry as a career will find it desirable to obtain a diploma in psychological medicine. Such a diploma is not at present compulsory for a permanent position on the staff of all mental hospitals, but it will probably become so in course of time, just as it is now essential to obtain the D.P.H. if a career in public health is contemplated. Psychiatry is one of the branches of medicine which candidates for the M.D. degree of the Universities of London and Edinburgh can take up, and, in addition, diplomas in psychological medicine (D.P.M.), to which reference has been made, can be obtained from the Universities of Cambridge, London, Edinburgh, Durham, Leeds, Manchester, Dublin, and the National University of Ireland, and from the Conjoint Board in England. The Royal Medico-Psychological Association of Great Britain and Ireland also grants certificates of proficiency after examination, and encourages the study of psychiatry by the offer of prizes for original and research work.

The requirements for a diploma differ to some extent in the various universities and colleges, but the following model scheme suggested by the Royal Medico-Psychological Association, and already adopted by the Royal College of Physicians of Ireland, will give an indication of the scope of the examination for a diploma.

Model Scheme for a Diploma in Psychological Medicine.

1. The candidate must be already a registered medical practitioner.

2. The candidate may present himself for examination on the subjects detailed under Part I of the curriculum (see para. 4) immediately he has concluded the prescribed courses of instruction, or can produce such other evidence of diligent study of the subjects to be examined upon as may be demanded. Part I must be passed save by special permission at least three months prior to entering for examination on Part II of the curriculum.

3. The candidate may not present himself for examination on the subjects detailed under Part II of the curriculum (see para. 4) until he has been a registered medical practitioner for not less than two years. He must, subsequently to qualification, have been in the practice of an approved mental hospital for not less than two years, or have attended for six months at a hospital, mental or general, for clinical instruction in psychological medicine, and subsequently held a resident appointment at an approved mental institution or mental wards of a general hospital for not less than six months. In both cases he must produce a certificate from a recognized source that he can apply his theoretical knowledge, and has practical acquaintance with, and is well and adequately versed in, the current clinical methods of examination and treatment of nervous and mental disorders. In the case of mental deficiency the certificate should include a practical knowledge of the various intelligence tests and other methods of ascertaining the degree of mental defect. He must also produce evidence of having attended, subsequently to qualification, courses of lectures, demonstrations or other evidence of diligent study of the subjects upon which he presents himself for Part II of the examination, as may be demanded.

4. Curriculum: Part I—(*a*) Anatomy, histology and physiology of the nervous system, including the autonomic system, anatomy and physiology of the endocrine glands, chemistry and cytology of the cerebro-spinal fluid. (*b*) Psychology, systematic and experimental. Part II—(*a*) Morbid anatomy, histology and pathology of the systems mentioned under Part I, (*a*) post-mortem and laboratory technique; (*b*) neurology and clinical neurology; (*c*) psychiatry (including the psychoneuroses), clinical psychiatry and the medico-legal relationships of mental disorders and mental deficiency. In addition, the candidate for Part II will need to show special knowledge of any one subject, to be selected by him from the subjects comprising Part I or Part II, or may choose to be examined in any one of the following subjects: (*d*) Mental deficiency and the mental disorders of childhood and adolescence, and the duties of school medical officers in relation thereto. (*e*) Bacteriology as applied to mental and nervous disease. (*f*) Psychopathology and psychotherapy. (*g*) The principles of diet, vitamins, and basal metabolism, and their application. (*h*) Eugenics and vital statistics. (*i*) Criminology and the jurisprudence of criminal responsibility.

5. The diploma, by request, may be endorsed that special knowledge has been shown in the subject selected.

6. It is suggested that any compulsory attendance at lectures or demonstrations and clinical courses should be limited to the subjects detailed for Part II, and that the course for Part I or Part II should not exceed eight weeks.

Mental Hospital Appointments.

Those who take up psychiatry as a career work as medical officers of public or private mental hospitals or similar institutions. Except in the larger institutions, such as those under the control of the London County Council, where a number of the medical officers are allowed to live out if married, the medical staff are resident officers, having board, lodging, etc., either in the hospital itself or a residence in the grounds. Junior assistant medical officers receive about £300 to £400 per annum, and senior assistant medical officers about £500 to £700, in both cases with board, lodging, laundry, etc., in addition; if married, the board, etc., is commuted for cash. As the mental hospitals are under local control the salaries vary much in different asylums. Medical superintendents, whose pay commonly ranges between £800 and £1,500 per annum, are provided with a house in the grounds of the hospital, and draw various allowances.

Since the passing of the Asylum Officers Superannuation Act of 1909, all officers and others of the established staff of a public (county or borough asylum) mental hospital may retire at the age of 55 on a pension varying from one-half to two-thirds of the value of their pay and emoluments, or one-fiftieth for every year served, paying as contribution 5 per cent. of the value of their appointments annually. This very favourable prospect may not appeal to junior practitioners joining the services, but will eventually prove to be a valuable asset.

Prospects in the Public Service.

Appointments to the public mental hospitals are made by the visiting committees, and in most cases only the junior posts are open to those who have not had previous experience in psychiatry. Since the public mental hospital service is a local and, except indirectly, not an imperial one, the promotion tends to be slow and uncertain; and the higher positions are not always advertised and thus thrown open to competition. For this and other reasons mental hospital work has undoubtedly not been in favour with newly qualified men in years past, but the general conditions of service have tended to show a progressive improvement, and will in all probability continue to do so in the future.

Both the British Medical Association and the Royal Medico-Psychological Association are working separately and together to improve present conditions of service, and have, for example, already removed the "celibacy" objection to the service. The salaries have also been considerably increased, especially in the junior ranks, and contrast favourably with those which were paid before the war. During the last few years considerable progress has been made in the conditions under which the insane are treated. The mental hospitals are developing an atmosphere approximating more closely to that of the general hospitals. As a result of these developments the mental hospital service is becoming more attractive, and now affords greater opportunities for the medical graduate who proposes to specialize in psychiatry.

While routine, administrative, and clerical work bulk largely in mental hospital duties, as they do in other public medical services, there is ample material, time, and scope for purely medical work and research—difficult as the subject may be—in psychiatry as one of the branches of medicine open to young graduates. Most mental hospitals are now equipped with efficient clinical laboratories; moreover, those who wish to undertake research are afforded every opportunity of doing so in the pathological department of the Maudsley Hospital and also in various other centres in England and Scotland. A change in the lunacy law, in which power was given to local authorities to make provision for the treatment of early and acute cases of mental disorder without certification, would do much to make psychiatric work more attractive to medical men. If this alteration in the law were made, hospitals, either in the precincts or the grounds of the county or borough mental hospitals, or in adjacent towns, would be erected in the course of time, or wards in general hospitals might be utilized for the same purpose. Such clinics would render appointments in mental hospitals more attractive because the work would be entirely free from the custodial aspects of mental disorder, and attention could be given by the physician to purely medical problems without irksome legal restrictions.

MAUDSLEY HOSPITAL, DENMARK HILL.

A course of instruction for the Diploma in Psychological Medicine is given annually at the Maudsley Hospital from January to May inclusive, the details of the last course being as follows. The course consisted of two parts. In the first part lectures on the anatomy of the nervous system were given by Professor Elliot Smith, with practical instruction by Mr. C. Geary. A course of lectures on the physiology of the nervous system, with demonstrations in physiological psychology, was given by Dr. F. Golla, a series of lectures and demonstrations on the biochemical aspects of mental disorders, and laboratory methods, by Captain S. A. Mann, and on theoretical and practical psychology by Dr. Henry Devine. For the second part of the course lectures on morbid psychology and psychiatry were given by Dr. Mapother, on the neuroses by Dr. Bernard Hart, on therapeutics by Dr. Petrie, on general pathology by Dr. Golla and Mr. C. Geary, and on pathological chemistry by Captain Mann. Dr. Bond lectured on the legal relationships of insanity, Dr. Shrubsall on mental deficiency, and Dr. East on criminal insanity. Dr. Golla and Dr. Walshe gave instruction on clinical neurology, and Mr. Foster Moore on eye changes as applied to psychiatry. The fee for the whole course (Part I and Part II) was 15 guineas, or for either part separately 10 guineas; for one single

series of lectures in Part I the fee was 4 guineas, and in Part II 2 guineas. Inquiries as to lectures, etc., should be addressed to the Director of the Central Pathological Laboratory, Maudsley Hospital, Denmark Hill, S.E.5.

BETHLEM ROYAL HOSPITAL.

A course will be held at Bethlem Royal Hospital, commencing on September 24th, of lectures and practical instruction for the Diploma in Psychological Medicine. It is proposed in future to give two courses each year—an autumn session of intensive character, commencing in September and completed in early December, and a spring session, commencing in the middle of January and completed in the middle of April. Each course consists of two parts: Part A includes lectures and demonstrations on the anatomy, histology, and physiology of the nervous system, with lectures on psychology and demonstrations in experimental psychology: Part B comprises lectures and clinical demonstrations in psychology, including lectures and demonstrations in the morbid anatomy of the nervous system, a series of lectures, with clinical demonstrations, on different branches of psychological medicine, and lectures, with clinical demonstrations, on mental deficiency. Entrants for the course who pay a composition fee of 15 guineas may, if due notice is given, attend either Part A or Part B of one course and postpone the other part until the next session. An entrant who wishes to attend one part only pays a fee of 10 guineas. An entrant who takes the complete course can attend the general clinical practice of the hospital on payment of 5 guineas for six months, or 10 guineas for one year, but an entrant who does not take either part of the course and desires to attend the clinical practice of the hospital must pay a fee of 5 guineas for each three months of attendance. To enable post-graduates to obtain special experience in this branch of medicine clinical assistants are appointed from time to time. Further particulars may be obtained from the Physician-superintendent, Bethlem Royal Hospital, S.E.1.

NATIONAL HOSPITAL, QUEEN SQUARE.

Post-graduate courses which fulfil the requirements of the regulations for the Diploma in Psychological Medicine in regard to instruction in nervous diseases are held at the National Hospital, Queen Square, Bloomsbury, W.C.1, thrice annually, usually during February to March, May to June, and October to November. Lectures on the anatomy, physiology, and pathology of the nervous system and various clinical lectures are delivered and demonstrations are given. Out-patient clinics are held at the hospital on the afternoons of Mondays, Tuesdays, Wednesdays, Thursdays, and Fridays. An inclusive fee of 10 guineas is charged for the whole course, but any part of the course can be taken separately at a special fee. A special arrangement is made for those unable to attend the whole course, and for details applications should be made to the dean of the medical school. Fees are payable to the secretary of the hospital on entering for the course.

TAVISTOCK SQUARE CLINIC FOR FUNCTIONAL NERVOUS DISORDERS.

Courses in the theory and practice of modern psychotherapy are held at this clinic about twice a year. Each course lasts a fortnight, and consists of about twenty lectures and ten seminars. These courses are intended for general practitioners interested in the subject and as an introduction for those who mean to specialize. They are open to senior students of medicine as well as to graduates. The subjects dealt with include the various schools of analytical psychology, treatment by persuasion and suggestion, differential diagnosis, and physical factors. Syllabus and particulars of dates and fees may be obtained from the Honorary Lecture Secretary at 51, Tavistock Square, London, W.C.1. Clinical assistantships are from time to time available for graduates who have attended such a course. The director of the clinic is Dr. H. Crichton Miller, the deputy director Dr. J. R. Rees, and there is a large children's department.

THE PUBLIC HEALTH MEDICAL SERVICES.

THE central authority to secure the adoption, effective carrying out, and co-ordination of measures conducive to the health of the people, and to promote research work and the proper training of persons for health services, is the Ministry of Health.

For the purpose of local public health administration the whole of England and Wales is divided into counties, county boroughs, boroughs, and urban and rural sanitary districts. The administrative County of London, exclusive of the City of London, is divided into twenty-eight metropolitan boroughs.

The public health medical services for Great Britain embrace between three and four thousand medical men and women who give whole-time services, and, in addition, a large number who give part-time services. The medical officers appointed for these services may be either medical officers of the Ministry of Health for England and of the corresponding Boards of Health for Scotland and Wales; or —and these form the large majority—they may be medical officers appointed by the many local public health authorities. These latter appointments include: medical officers of health, tuberculosis medical officers, maternity and child welfare medical officers, venereal diseases medical officers, and school medical officers—who must be regarded as working in the health interests of the school child. By the larger public health authorities assistant medical officers are also appointed, and these posts often serve as stepping-stones to the higher offices as vacancies, which are required to be advertised, occur.

A scale of remuneration for services has been recommended, quite recently, by a conference of representatives of the British Medical Association, the Society of Medical Officers of Health, and of the local authorities. The scale, if approved by all the parties, will be valid for the period of five years from April 1st, 1930. It provides a minimum commencing salary for a whole-time medical officer of health in a place of 50,000 population or under of £800: 75,000 population, £900; 100,000, £1,000; rising to £1,800 where the population exceeds 750,000. These amounts are somewhat less in counties and other rural areas and in the smaller municipal boroughs. The scale for medical superintendents of institutions other than mental hospitals varies from £750 minimum commencing salary for 150 beds or under to £1,100 for hospitals with more than 750 beds. The minimum for resident medical officers in hospitals, sanatoriums, and other institutions without responsibility for the work of other medical officers is £350, with board, lodging, laundry, and attendance, and this rises to £450; departmental officers to begin at £500, rising to £700, senior medical officers in full charge of services or departments officers, £750 to £1,000 to begin with, according to responsibility and scope.

THE MEDICAL SERVICES OF THE CENTRAL AUTHORITY.

For England, the medical work of the Ministry of Health has been organized under the control of a Chief Medical Officer. It is subdivided into seven sections, with a senior medical officer at the head of each, and about a hundred medical officers, of whom about half are regional and deputy regional medical officers employed for certain duties under the Health Insurance Acts. Briefly, the sections deal with environmental hygiene, epidemiology, and international health; maternity and child welfare; tuberculosis and venereal diseases; the supervision of the food supplies; sanitary administration in relation to infectious diseases; national health insurance; and the school medical service. Vacancies in the staff are advertised from time to time in the medical journals, and appointments are made by the Minister on the recommendations of a Selection Committee. They are Civil Service appointments, subject to the usual conditions as to pension, holidays, etc. Medical officers are also employed by the Welsh Board of Health (Cardiff) and the Department of Health for Scotland (Edinburgh).

MEDICAL OFFICERS OF HEALTH.

The duties of the medical officer of health are to inform himself upon all influences affecting, or threatening to affect, injuriously the public health within his district; to advise his sanitary authority upon all matters relating to health, and to perform all the duties imposed upon him by statutes, by-laws, and regulations. He must prepare and submit to his local authority special and annual reports; give immediate information to the Ministry of Health of any serious outbreak of disease; and, subject to the instruction of his sanitary authority, he shall direct or superintend the work of sanitary inspection.

By the Sanitary Officers Order, 1926, no person is qualified to be hereafter appointed or reappointed as a medical officer of health of any district or combination of districts unless, in addition to the qualifications prescribed by any statute, he is also either registered in the *Medical Register* as the holder of a Diploma in Public Health, Sanitary Science, or State Medicine, or has had not less than three years' previous experience of the duties of a medical officer of health.

The Public Health (Officers) Act, 1921, which was promoted by the British Medical Association, provides that a whole-time medical officer of health of a county borough or urban and rural district in England and Wales, a part of whose salary is contributed by the Exchequer, shall not be appointed for a limited period, and shall not be removed from his office except by or with the consent of the Minister of Health. A similar security of tenure also applies to the medical officers of health of county councils and of London boroughs.

Under the Sanitary Officers Order, 1926, a medical officer of health who does not devote his whole time to the duties of his office, but a portion of whose salary is obtained from Exchequer grant, may be appointed without limit of time; in which case he cannot be removed from office without the consent of the Minister. If he is appointed for a specified term, say one year, he continues to hold office from year to year unless the Minister consents to his removal. Where the electing body pays the whole of the salary of a medical officer of health he may be dismissed from office without reference to the Minister of Health.

A considerable number of authorities have now adopted the Local Government and Other Officers Superannuation Act, 1922. Under this Act if an officer is incapacitated by ill health after ten years of service, or if he has reached 65 years of age, he is entitled to superannuation on the following scale: after ten years' service, 10/60 of the average salary which he received during the last five years of employment; after eleven years, 11/60, and so on up to a maximum of 40/60 after forty years or more of service. This Act, however, remains permissive, and it fails to make due allowance, in computing service for purposes of superannuation, for the more advanced age, as compared with other officers, at which the medical officer of health can enter the public service. In these two respects the position reached falls short of that for which the British Medical Association has been working for some years.

In Scotland the position is different in some respects. The central authority is the Board of Health, with a staff of medical officers for health insurance work. Under the Public Health (Scotland) Act, 1897, no one can be appointed as medical officer of health for any area unless he possesses the Diploma in Public Health. No medical officer can be removed from office except with the sanction of the Board of Health. A "proper" salary must be paid, and the local authority may not bring about the resignation of the officer by indirect means, such as reducing the salary or attaching new conditions to the appointment. The Act says nothing about superannuation or the age of retirement.

SCHOOL MEDICAL OFFICERS.

School medical officers are appointed by local education authorities. Primarily their duty is to detect among the children attending the public elementary schools any physical or mental defect which may retard education, and to inform their parents of its existence. Most approved schemes of medical inspection include arrangements which facilitate the task of parents in obtaining for their children the necessary treatment, check the results of this treatment, and keep each defective child under skilled observation both at home and at school until it has passed altogether out of the education authorities' hands. Indeed, it is now the practice for the education authorities themselves to provide for certain ameliorative work, notably the prescription of glasses where necessary, dental treatment, the removal of adenoids and tonsils, and treatment in connexion with certain diseases of the skin, and some physical and mental defects. The general effect of all schemes alike is to make the inspection imposed by law of benefit, not merely to the individual child, but to the community at large, by preventing the development of conditions which lead to the existence of a large proportion of inefficient citizens among the adult population. The work is so related to that of medical officers of health that, as a rule, the senior school medical officer fills both appointments, his work, when necessary, being supplemented by that of whole- or part-time assistants. A Diploma in Public Health is almost always required of those entering the school medical service.

In Scotland, while the statutory authority for the work of the school medical service is different, the scheme of work is broadly the same.

TUBERCULOSIS MEDICAL OFFICERS.

A tuberculosis medical officer is a whole-time officer with special training and experience in tuberculosis work, and of a suitable age and attainments to command general confidence. In England and Wales such officers are appointed by county councils and county borough councils, and their duties are to carry out the work of diagnosis of tuberculosis, to advise as to treatment, and to take charge of the work of tuberculosis dispensaries and sanatoriums where these are in operation. The work under tuberculosis schemes is co-ordinated with the general public health work of local authorities, and so the medical officer of health is often appointed as the chief tuberculosis officer when a special tuberculosis officer is on the staff of the local authority. The arrangements in Scotland are very similar.

MATERNITY AND CHILD WELFARE MEDICAL OFFICERS.

Any public health local authority, however small, may make arrangements for maternity and child welfare work within its area, although very generally the smaller local authorities are provided for in county council schemes. For the schemes of the smaller local authorities the services of a part-time medical officer are obtained when the medical officer of health does not himself undertake the duties; but for the larger schemes special whole-time appointments are made. The maternity and child welfare medical officer is responsible for the work at the centres provided and for directing the home visitations; and the whole of these activities is closely co-ordinated with the other branches of public health work directed by the medical officer of health.

Much of this work was commenced in different parts of the country by voluntary organizations; some of it still remains in their hands, and is only loosely linked up with the public health local authority; but the tendency is for the whole of it to be undertaken by the local authorities. A large number of women medical officers have been appointed to these posts during recent years.

VENEREAL DISEASES OFFICERS.

Schemes for the diagnosis and treatment of venereal diseases are provided and administered by county councils and county borough councils. In some cases the officer is on the whole-time public health staff, and in others he is a part-time official. Special knowledge and practical experience in the treatment of venereal diseases are essential. The officer appointed for either whole-time or part-time service works at one or more clinics, and also gives instructions and assistance in the treatment of venereal diseases to general practitioners, who are allowed to attend the clinics.

REMUNERATION IN THE PUBLIC HEALTH SERVICE.

In order to ensure that public health authorities may obtain skilled and highly trained medical officers it is essential that such officers should receive salaries commensurate with their attainments, bearing a reasonable relationship to the time and money expended in fitting them for their important and responsible duties, and comparing well with the income which might be secured in other lines of medical work. With this end in view the British Medical Association and the Society of Medical Officers of Health prepared a scale of minimum commencing salaries for whole-time public health medical officers.

The scale, which was put into operation in 1925, has been attended with a large measure of success, and obtains in England, Northern Ireland, and in Scotland (with modifications). The salaries laid down in this scale are briefly as follows:

Resident medical officers at hospitals, sanatoriums, etc., without responsibility for the work of other medical officers: £350 a year, *plus* emoluments.

Medical officers employed in departments, working under a senior medical officer and without responsibility for the work of other medical officers: £600 a year.

Senior medical officers (not medical officers of health) in charge of services or departments: £750 to £1,100, according to responsibility and scope of department.

Deputy or chief assistant medical officers (hospitals, sanatoriums, etc.): a salary equal to 60 per cent. of the salary of the medical superintendent or senior medical officer in charge.

Medical officers of health: the salaries are graded according to population, from £800 to £1,800.

During the past year there has been a series of conferences between representatives of the Associations of Local Authorities and the British Medical Association under the chairmanship of Lord Askwith, and an agreement was arrived at which will materially modify the above scale in several important particulars, the chief being that in all the main categories except that of the medical officer of health arrangements are made for regular increments rising to a maximum. This scale was published in the *Supplement* of July 27th (p. 71), was ratified by the Representative Body of the British Medical Association at Manchester, and now awaits ratification at the hands of the Associations of Local Authorities. If and when so ratified it will come into force on April 1st, 1930, and holds good for five years, at the end of which time notice may be given by any of the contracting bodies to terminate it or to modify it. In the meantime, the old scale will be used by the British Medical Association, subject to such adaptations as may seem equitable in the circumstances.

During the last twelve months 95.3 per cent. of the whole-time public health appointments have been made at salaries in accordance with the scale.

For the right class of practitioner with leanings in the direction of public health work the service offers a successful career, but it must always be remembered that there are comparatively few posts which carry the higher salaries.

THE REGULATIONS FOR THE DIPLOMA IN PUBLIC HEALTH.

The Examination.

By the most recent Regulations or Rules of the General Medical Council, which came into force on January 1st, 1924, the examination for the D.P.H. is divided into two parts, and no candidate is allowed to sit for the final part of the examination until two years have elapsed since a registrable qualification was obtained. The object of this two years' interval is "to provide opportunity for candidates for the Diploma or Degree in Sanitary Science, Public Health, or State Medicine to pass from the state of pupilage to that of responsible practitioners, to give mature consideration to the obligations and duties involved in the work of the Public Health Service, and to acquire direct experience of medical work in a responsible capacity either in practice or in hospital or laboratory appointments."

The examination is both written and oral, and must include a practical examination in bacteriology and chemistry (Part I), and in infectious diseases, food inspection, inspection of premises, dwellings, factories, workshops, schools, etc. (Part II).

Any candidate from the Dominions who possesses qualifications registrable in this country is eligible as a candidate for the examination, given that he has received such a course of training as that defined by the Regulations, at an institution which is approved by the General Medical Council.

The Curriculum for the Diploma in Public Health.

The curriculum must extend over a period of twelve months, and a candidate is admitted to either part of the examination after he has completed the prescribed courses of instruction in the subjects thereof. At least five months must be given to practical laboratory instruction in an institution approved by the licensing body, in the subjects:

(1) Bacteriology and parasitology, including entomology, especially in relation to diseases of man and to those diseases transmissible to man from the lower animals (180 hours of such instruction is required).

(2) Chemistry and physics in relation to public health (90 hours of such instruction is required).

(3) Meteorology and climatology (10 hours of such instruction is required).

Therefore at least 280 hours of practical instruction, extending over a period of at least five months, is demanded before a candidate is eligible for Part I of the examination.

For a candidate to become eligible for Part II of the examination he must first receive instruction in:

(1) Principles of public health and sanitation (for approximately 30 hours).

(2) Epidemiology and vital statistics (approximately 20 hours).

(3) Sanitary law and administration, including public medical services (approximately 20 hours).

(4) Sanitary construction and planning (approximately 10 hours).

(5) Every candidate must also have made thirty attendances, of not less than two hours in each week of a three-months' period, at the clinical practice of a recognized hospital for infectious diseases; and he must have received instruction in methods of administration.

(6) Every candidate must produce evidence that he has, during a period of not less than six months, been engaged in acquiring a practical knowledge of the duties, routine and special, of public health administration under the supervision of a medical officer of health, who shall certify that the candidate has received, from this officer or other competent medical officer, during not less than three hours on each of sixty working days, practical instruction in these duties, and those relating to:

(*a*) Maternity and child welfare service;
(*b*) Health service for children of school age;
(*c*) Venereal diseases service;
(*d*) Tuberculosis service;
(*e*) Industrial hygiene;
(*f*) Inspection and control of food, including meat and milk.

Certificates of having received the prescribed instruction in public health administration must be given by a medical officer of health who devotes his whole time to public health work; or by the medical officer of health of a sanitary area having a population of not less than 50,000; or in Ireland by the medical superintendent officer of health of a county or county borough having a population of not less than 50,000.

TRAINING AND EXAMINING CENTRES FOR PUBLIC HEALTH QUALIFICATIONS.

Degrees in Sanitary Science are conferred, in England, by the Universities of London, Durham, Liverpool, and Birmingham; in Scotland, by the Universities of Glasgow and Edinburgh; and in Ireland, by the University Colleges of Dublin and Cork. In most cases these degrees are conferred only upon medical graduates of the universities granting them.

Whereas for the Diploma of Public Health the requirements of the General Medical Council are strictly conformed to, these requirements are extended, as a rule, as to both the period and the scope of special studies demanded, before Degrees in Sanitary Science are granted.

Almost all the universities of Great Britain and Ireland grant a D.P.H. and provide for the necessary training. The English and Scottish Conjoint Boards and the Irish Colleges also grant these diplomas.

From September of this year the post-graduate teaching and training in public health, in London, will be provided mainly at one centre—the London School of Hygiene and Tropical Medicine (University of London); the only

other training centre which will continue to offer such facilities being the Royal Institute of Public Health.

The course of study for the D.P.H., as provided by the London School of Hygiene and Tropical Medicine, covers a period of twelve calendar months, and is so designed that students wishing to do so can proceed to a new academic diploma instituted by the University of London. The School will undertake research work in preventive medicine, and members of the public health services will have a common room placed at their disposal, and will be privileged to attend staff and special lectures.

The Royal Naval Medical College and the Royal Army Medical College provide courses of training to the medical officers of these two services.

Degrees and Diplomas in Public Health are registrable qualifications, but not so those in Tropical Medicine and Hygiene.

Qualifications in Tropical Medicine and Hygiene.

The University of London grants a degree (M.D. in Tropical Medicine) to their medical graduates, and the course of training required must extend over at least one academic year.

Diplomas in Tropical Medicine and Hygiene are granted, in England, by the Universities of Cambridge and Liverpool, and by the English Conjoint Board; and, in Scotland, by the University of Edinburgh. Among the institutions which provide qualifying courses are the London School of Hygiene and Tropical Medicine, the Liverpool School of Tropical Medicine, and the Royal Army Medical College. In the last-mentioned institution the training provided is restricted to army medical officers. The training period for these diplomas is about six months. Graduates of medicine and surgery of recognized universities whose degrees are not registrable in this country may enter for the examination of the English Conjoint Board, and the conditions of study may be modified on the grounds of previous work in the tropics or of original investigations undertaken.

The Colonial Office has decreed recently that the holder of a D.T.M. and H., or of a D.T.H., is eligible for appointment as a medical officer of health in places and districts other than those with large populations. In the latter cases a D.P.H. is required.

Those wishing for the details of syllabus of study, fees, date of commencement of the training courses, and the dates of examinations, etc., of any particular training course or examining body, will find these fully and clearly set out, with notes and comments, in the *Guide to the Regulations, Courses and Examinations for Qualifications in Public Health and Tropical Medicine and Hygiene in Great Britain and Ireland*, which has been prepared recently by Dr. Andrew Balfour, C.B., C.M.G., D.P.H., and published by the British Medical Association (Tavistock Square, W.C.1). The price is 3s. net.

The University of Manchester has a well-equipped department of bacteriology and preventive medicine, where candidates preparing for the examinations of the various university and examining boards for the Diploma in Public Health can obtain instruction. It also prepares candidates for the Diploma in Bacteriology and in Veterinary State Medicine, granted by the university, and for its Certificates in Factory Hygiene and School Hygiene. Full particulars can be obtained from the Dean of the Medical School, the University, Manchester.

The University of Edinburgh grants a Diploma in Public Health. The course, which extends over a period of twelve calendar months, can be commenced in October only, and provision is made by the university for instruction in all the subjects. Candidates for the diploma must be graduates in medicine and surgery of the University of Edinburgh, or must hold corresponding degrees or registrable medical qualifications, which must be registered before a candidate is admitted to examination. The course for the diploma is divided into two parts, for each of which examinations are held twice annually—*in* March and July for Part I, and in October and March for Part II. In each part the candidate must pass in all the specified subjects at one examination. Admission to the examinations is contingent upon the candidate having complied with the following conditions:

PART I.—(*a*) Completion, subsequent to obtaining a registrable medical qualification, of the course of instruction prescribed for Part I.

PART II.—(*b*) Completion, subsequent to obtaining a registrable medical qualification, of the course of instruction prescribed for Part II. (*c*) A lapse of two years after obtaining a registrable medical qualification. (*d*) Previous passage of examination in all subjects of Part I.

Further particulars can be obtained from the Dean of the Faculty of Medicine, Edinburgh.

THE NAVY, ARMY, AIR FORCE, AND INDIAN MEDICAL SERVICES.

THE rates of pay and conditions of service for the Royal Naval Medical Service, the Royal Army Medical Corps, the Royal Air Force Medical Service, and the Indian Medical Service are considered by the British Medical Association to be satisfactory. In point of fact, the present conditions of service, more particularly in the case of the R.A.M.C. and I.M.S., are largely the result of the action of the Association. In fulfilment of the desire of the Association to assist in recruiting these services we publish below full particulars.

There still appears to be considerable difficulty in getting a sufficient number of young medical officers to enter any of these services, and the Association desires to point out that in its opinion the prospects in them are both financially and professionally good, and that there is no reason why young men recently qualified should not enter them. In the case of the R.A.M.C. the prospects of rapid promotion are particularly good, owing to the prolonged shortage of candidates since the war. Another important point should be noted—namely, the concession, in the case of the R.N.M.S., R.A.M.C., and R.A.F.M.S., by which a newly qualified medical man can hold a hospital appointment for one year before entering the services, counting it as a year of service towards promotion and retirement.

ROYAL NAVAL MEDICAL SERVICE.

A CAREER as a medical officer in the Royal Navy offers very definite attractions. In the large naval hospitals the medical, surgical, and specialist work is of a very high standard. The work is exacting, and it is the aim of the Admiralty to arrange appointments as far as possible so that medical officers have an opportunity of alternating their work not only at home and abroad, but also ashore and afloat.

To give naval surgeons opportunities for professional work has always been a very definite policy of the Admiralty, and within the last year or so this matter has received still further attention. The general and specialist courses have been increased so that, as far as possible, every officer shall have a course of instruction of not less than four months' duration every four years. The number of specialists allowed is now sixty, and the specialist allowance is 5s. a day. The establishment of Surgeon Captains has been increased to twenty, and every recent improvement has been made towards giving increased opportunities of advancement and accelerated promotion to the best men.

Examinations for direct entry into the Medical Service are at present in abeyance. Entries are made by means of the short-service scheme.

General Conditions of the Short-service Scheme.

A candidate must be registered, must be under 30 years of age, and must be recommended by the dean of his school; if, however, the candidate *intends to* apply for transfer to the permanent list, he must have been under 28 years of age at the time of his entry. He must be a British subject of pure European descent. *Unmarried candidates will* be preferred. A candidate will be interviewed by the Medical Director-General R.N., and will undergo a physical examination. If considered eligible by the Medical Director-General his name will be *submitted* to the Board of Admiralty, and he may be appointed "surgeon lieutenant for short service." A candidate must engage for three years, with the option of continuing for a further period of twelve months if his services are still required. The present rate

of pay is £1 4s. 10d. a day or £453 4s. 2d. a year, with the same allowances as are payable to permanent officers of their rank. Lodging money at the rate of £80 a year is usually allowed when employed on shore, without quarters in the United Kingdom, and £56 10s. a year in lieu of rations when not victualled in kind. Medical officers entering the Navy will be eligible, at the discretion of the Admiralty, to have their seniority antedated up to a limit of one year if they have held previously a resident appointment in a civil hospital for not less than this period. Such an appointment must be one recognized by the Admiralty for this purpose, and must not have terminated more than six months before entry into the service. On joining an allowance of £50 for uniform is made.

An officer engaged for three years is entitled to receive two months' notice of his services being no longer required. A gratuity of £8 6s. 8d. will be payable to officers for each completed month of service on completion of their period of service, or to any who are invalided for causes not within their own control before the completion of the prescribed period.

Transfer to Permanent Service.

A short-service surgeon lieutenant, after six months' service, may be considered, on application to the Secretary of the Admiralty, for transfer to the permanent service, and would be permitted to count his seniority from the date of entry for short service for purposes of promotion, increment of full pay, and for retired pay; but for purposes of retiring gratuity on the permanent officers' scale his service will reckon only from the date of transfer to the permanent list.

Officers entered for short service who are eligible for the grant of increased seniority in respect of time served in civil hospital appointments will only be allowed the antedate of seniority if they apply to transfer to the permanent list within eighteen months of their date of entry.

Courses of instruction in clinical medicine, surgery, and allied subjects are normally provided once in every four years for all officers below the rank of Surgeon Captain, and on completion of the courses officers will be appointed to a large naval hospital unless and until they receive appointments elsewhere. Courses in connexion with civil hospitals in London or other teaching centres are also arranged at intervals for those selected to hold specialist appointments. In addition, opportunities are given for medical officers to take post-graduate courses prior to sitting for the higher examinations.

Rates of Pay.

The current rates of full pay and retired pay are set out below. They represent a deduction of 6 per cent. from the standard rates which were fixed in 1920, when the cost of living was high; 20 per cent. of the standard rate is regarded as variable as the cost of living rises or falls. The next revision will be on July 1st, 1930.

Full Pay.

	Current Rate per annum. £ s. d.
Surgeon Lieutenant on entry	410 12 6
After 3 years	498 16 8
(Surgeon Lieutenants usually receive promotion after 6 years' service.)	
Surgeon Lieutenant Commander on promotion ...	599 4 2
After 3 years	635 14 2
(Surgeon Lieutenant Commanders usually receive promotion after 12 years' total service.)	
Surgeon Commander on promotion	772 11 8
After 3 years	839 10 0
After 6 years	909 9 2
After 9 years	976 7 6
Surgeon Captain on promotion (promotion is by selection)	1,115 5 10
After 3 years	1,201 9 2
After 6 years	1,286 12 6
Surgeon Rear-Admiral (promotion is by selection)	1,780 13 4
Medical Director-General (Surgeon Vice-Admiral)...	2,350 0 0

There are also allowances which form a substantial addition to the rates of pay. There are sixty specialist appointments open to medical officers. They comprise specialist posts in medicine, surgery, diseases of the eye, ear, nose, and throat, radiology, hygiene, etc., and an allowance at the rate of 5s. a day is payable to holders of them.

Medical officers in charge of naval hospitals and sick quarters receive charge pay on the following scale:

Surgeon Rear-Admirals and Surgeon Captains ...	10s. a day.
Surgeon Commanders	5s. a day.

Maximum Retired Pay.

(Approximate current rates.)

	£	Age for compulsory retirement.
Surgeon Vice-Admiral	1,123	On vacating office.
Surgeon Rear-Admiral	950	 60
Surgeon Captain	846	 55
Surgeon Commander	564	 50
Surgeon Lieutenant Commander and Surgeon Lieutenant	423	 45

Thus an officer who is not promoted above the rank of Surgeon Commander would be compulsorily retired at the age of 50.

Gratuities on Retirement.

The following gratuities are payable if an officer of the permanent list is permitted to retire voluntarily:

	£
After 4 years' full-pay service...	500
„ 8 „ „ „	1,000
„ 12 „ „ „	1,500
„ 16 „ „ „	2,250

Surgeon Lieutenants for short service, transferred to the permanent list, will only be allowed to retire with a gratuity after four years' full-pay service from the date of such transfer.

Further Particulars.

Full particulars and a form of declaration can be obtained from the Medical Director-General, Admiralty, Queen Anne's Chambers, Tothill Street, London, S.W.1.

ARMY MEDICAL SERVICE.

ENTRANCE to the Royal Army Medical Corps, either by competitive examination or by selection, as decided by the Army Council, will take place half-yearly, in January and July. The examinations in medicine and surgery are entirely of a clinical and practical character, partly written and partly oral. The regulations for admission, giving full details, can be obtained from the Under Secretary of State (A.M.D.1), War Office, Whitehall, London, S.W.1. A personal interview with a representative of the Director-General, Army Medical Services, is readily obtainable. The rates of pay and allowances are good; the opportunities of post-graduate study are generous, and the work is varied, responsible, and interesting. The gratuities after certain periods of service enable an officer, should he so desire, to leave the service with a capital sum large enough to go a long way towards re-establishing himself in civil life, and, further, the knowledge of the world and the comradeship of his fellow officers that he has gained in the army will be of no small value to him.

New entrants, who must be 22 and not over 28 years of age, are commissioned in the rank of lieutenant, and the first six months of service are spent on probation, during which time they undergo, in addition to their military training at the Royal Army Medical Corps School of Instruction at Aldershot, a probationary course at the Royal Army Medical College in London in hygiene, pathology, tropical medicine, military surgery, organization of military hospitals, and principles governing medical charge of troops. At the end of this course, and after qualifying at the necessary examinations, their commissions are confirmed and they take their places in seniority according to the total marks obtained at all examinations up to that date. Officers' Training Corps service with possession of certificate "A" or "B" (medical) carry a definite value in marks in this total.

An entrant who is holding or about to hold at the time of the entrance examination a resident house appointment at an approved civil hospital may be seconded while holding such an appointment up to a maximum period of twelve months. A candidate who has held such an appointment within six months of entry may be granted an antedate up to twelve months in respect of the period the appointment was held. This secondment and antedate counts in all respects as commissioned service, except that pay will not be issued for that period.

After a total period of one year's service at home, the young officer goes abroad, probably to India, for his first tour of foreign service. Here he gains his first practical experience of tropical disease and tropical hygiene. His tour abroad lasts five years, with probably six months' leave home during that time. On returning home the R.A.M.C. officer has the opportunity to decide whether he will remain in the corps or accept the gratuity of £1,000 after seven years' service and try his fortune in civil life. If he elects to remain, he will, between his eighth and twelfth year of service, undergo a course of post-graduate study at the Royal Army Medical College and the London hospitals of five months' duration, followed by a course of study of a special subject selected by himself provided he has shown special aptitude in the post-graduate course or during his previous service. During this period of study he remains on full pay and the fees of the courses are paid by the State. When qualified in his special subject the officer is eligible for a specialist appointment. The total number of these appointments is 104 and the additional rate of pay 4s. 8d. a day. After this post-graduate course the officer probably proceeds abroad again and promotion to major rapidly ensues, and from that time onward he receives regular successive increases of pay and is eligible for additional and charge pay as well. The directorates of hygiene and pathology and the appointment of two serving officers as consultants in medicine and surgery have been instituted, and have proved a marked success. All these appointments are of the rank of colonel or major-general, and were devised to permit specially selected officers to rise through all ranks to that of major-general on the strength of their professional or purely scientific work.

Under these conditions the possibilities for good workers are very great in the Royal Army Medical Corps. There

is scope for original research in tropical disease, in preventive medicine, and in bacteriology, as well as in the large clinical field open to the specialist in medicine, surgery, or gynaecology, in venereal disease, and in ophthalmology. Child welfare is also undertaken systematically by officers of the Royal Army Medical Corps. At the same time, instruction in administration is continuous. There are also many appointments carrying administrative responsibility to those officers who display capacity for this duty.

Promotion.

Promotion takes place automatically to captain after three and a half years' and to major after twelve years' service, provided the officer is qualified and recommended for promotion. Promotion to the higher ranks is by selection from those senior in the rank below, but special promotion by brevet or otherwise is open to officers of the Royal Army Medical Corps.

Pay and Allowances.

The rates of pay and allowances are given in the accompanying table (see below). In addition, an officer at home in charge of a hospital receives charge pay, the daily amounts being from 2s. 6d. to 10s., according to the number of beds. There are other appointments for which charge pay is given from 5s. to 10s. daily.

Retirement and Retired Pay.

Retired pay will consist of two parts: (*a*) a service element based on the officer's total service; (*b*) a rank element for the substantive rank from which the officer retires. An officer with less than twenty complete years' service will not be eligible for retired pay on voluntary retirement. The scale, subject to the reduction of 6 per cent. referred to below is, for the service element, £15 a year for each completed year of service as a medical officer. For the rank element the scale is as follows:

Substantive Rank from which Retired.	After Completing 1 Year's Service in the Rank.	After Completing each Additional Year's Service.	Maximum Rank Element.
	£	£	£
Major	12	12	120
Lieutenant-Colonel	150	30	240
Colonel	290	50	390
Major-General	440	50	540
Lieutenant-General... ...	590	50	690

The retired pay of an officer retiring with less than one complete year's service in the rank from which he retires will be assessed as though he had retired from the rank below.

The maximum standard rates of retired pay are as follows:

Captain and Subaltern	£300
Major	£450
Lieutenant-Colonel	£600
Colonel	£800
Major-General	£1,000
Lieutenant-General	£1,200

The above rates are those laid down in the Pay Warrant. They have been reduced by 6 per cent. as from July 1st, 1927. Further revision may take place triennially to an extent not exceeding 20 per cent., according to variation in the cost of living.

Officers with seven and less than twenty years' service as medical officers may be permitted to retire with a gratuity in accordance with the following scale:

After 7 years' service as a medical officer	£1,000
After 15 years' service as a medical officer	£2,800
After 18 years' service as a medical officer	£3,500

Seconded Service.

An officer may be permitted to accept employment in the Foreign or Colonial Offices; when so seconded he is not eligible for pay or allowances from army funds, but his service continues to reckon towards promotion and, under certain conditions, towards increase of pay, pension, or gratuity.

Service on the West Coast of Africa.

Officers for service in West Africa are usually taken from a list of volunteers for such service. An officer at present receives, while actually serving in West Africa (which service may include ordinary leave not exceeding sixty-one days in a year, and any time spent at Madeira or the Canary Islands on sick leave), additional pay at the following daily rates: lieutenant-colonel 12s., major 9s., captain 7s. 6d., lieutenant 6s. Service on the West Coast of Africa also counts double towards voluntary retirement and the service element of retired pay under certain conditions, and also entitles to leave at home of one day for every two days' service after twelve months' continuous service on the coast. Continuous service includes the ordinary sixty-one days' leave and any time spent in Madeira or the Canary Islands on sick leave for this purpose.

THE ARMY DENTAL CORPS.

The corps is administered by the Director-General, Army Medical Services. It is a joint service for the Army and Royal Air Force, and the personnel is required to serve under either force and be interchangeable. The regulations for admission to the Army Dental Corps should be obtained from the Under Secretary of State, War Office.

Pay and Allowances at Home.

Rank.	Pay per Diem.*	Rations.†	Servant.	Married.			Unmarried.		Total per annum.

* Married rate of pay is not admissible to officers whose age is under 30.

ROYAL AIR FORCE MEDICAL SERVICE.

THE Air Council attaches great importance to attracting into the R.A.F.M.S. the best type of medical man, since on the capacity of the medical service depends in a peculiar degree the safety and efficiency of the Royal Air Force. The duties of these medical officers include, not only the prevention and treatment of those ordinary diseases to which the personnel of any fighting service are liable, but the special study of the mental and physical stresses imposed on the airman in diverse circumstances and climates—a new branch of medicine which still provides considerable scope for research.

As promotion to the higher ranks of the service is by selection from officers who are eligible by reason of length of service, and as a certain proportion of the higher ranks will be reserved for purely professional as opposed to administrative appointments, it will be seen that there are excellent prospects for the young medical officer who exhibits ability and energy in professional work as well as for those who develop a talent for administration. Duties will, as a matter of course, give him flying experience as a passenger, which is necessary for the proper study of the medical problems of aviation and for gaining first-hand knowledge of the conditions under which his comrades serve.

Commissions.

The establishment will consist partly of permanent and partly of short-service officers.

An officer will, on first entry, be granted a short-service commission for a period of three years on the active list (which may be extended to five years at the discretion of the Air Council, if the officer so wishes, on the recommendation of the Director of Medical Services) and of four years in the Reserve of Air Force Officers. Selections for permanent commissions will be made from officers holding short-service commissions, and those who are not selected will be transferred to the Reserve at the expiration of their period of service on the active list. For those entrants who desire it, the prospect of obtaining a permanent commission is approximately an even one.

Arrangements are in force under which an officer granted a short-service commission who has previously held a resident appointment in a recognized civil hospital may, subject to certain conditions as to the length of the appointment and the interval between its termination and date of commission, be granted an antedate of the commission equal to the period of the appointment up to a maximum of one year.

A similar arrangement obtains as regards a recognized hospital appointment which is held or about to be held at the date when the short-service commission is granted.

An officer who has been seconded or whose commission has been antedated as above will be required to serve for a minimum period of three years on the active list from the date of joining for actual R.A.F. duty.

Officers who have been selected for permanent commissions may be permitted to attend, for a period not exceeding nine months, a post-graduate course in general medicine and surgery, tropical and preventive medicine, and other special subjects. Such permission may be granted at any time when the exigencies of the service permit during the first sixteen years of service, and when attending these courses officers will receive full pay and allowances.

New entrants into the R.A.F.M.S. will be commissioned as Flying Officers (Medical), and will be eligible for promotion to the rank of Flight Lieutenant (Medical) after two years' service. Officers selected for permanent commissions will normally be promoted to the rank of Squadron Leader after ten years' total service. Accelerated promotion may be granted in a limited number of cases to officers who show exceptional ability after the completion of eight years' service. Promotion within establishment to the rank of Wing Commander will be by selection at any period after sixteen years' total service, and to that of Group Captain by selection at any period after twenty-two years' service.

There will be no competitive examination on entry; candidates must be under 28 years of age, be British subjects, the sons of British subjects, and of pure European descent, and will be interviewed by a Selection Board at the Air Ministry, London, presided over by the Director of Medical Services, Royal Air Force, before acceptance, and will be required to pass a medical examination.

On appointment entrants will undergo an initial course, during which they will be given instruction in the special medical aspects of aviation; the organization and administration of the Royal Air Force; and the general and special duties to be performed by officers in the Medical Branch.

Uniform Allowance.

An allowance of £50 towards the cost of uniform is made on joining to candidates who have not had previous commissioned service in H.M. Forces.

Pay and Allowances.

The emoluments of medical officers of the Royal Air Force are given in outline on page 420. The standard rates of pay and retired pay were drawn up on the basis of the high cost of living in 1919, and 20 per cent. of each of the standard rates is detachable and subject to alteration, either upwards or downwards, as the cost of living rises or falls. Under this provision the current rates now in force represent a reduction of approximately 6 per cent. on the standard rates. The next revision will take effect from July 1st, 1930, and subsequent revisions will be made at intervals of three years.

Retired Pay.

The minimum period of service qualifying for retirement on retired pay is twenty years. Standard rates of retired pay are as follows:

Air Officers.—Air Vice-Marshal, £790 to £1,010 per annum; Air Commodore, £650 to £950 per annum.

RETIRED PAY (PERMANENT OFFICERS).

Officers Below Air Rank.

Age on Retirement.	Standard Yearly Rate of Retired Pay.	Years of Service.	Addition for each Extra Year of Service.*	Deduction for each Deficient Year of Service.*
	£		£	£
40	300	17	15	15
41	337	17	15	15
42	375	18	15	15

53	742	23	22	15
54	765	24	22	15
55	790	24	22	15

* Limited to five years.

The maximum standard rates of retired pay and the compulsory retiring ages for the several ranks are :

Rank.	Yearly Rate of Retired Pay.	Compulsory Retiring Age.
	£	
Air Vice-Marshal	1,010	60
Air Commodore	950	57
Group Captain	900	55
Wing Commander	600	51
Squadron Leader .	500	48

Gratuities.

A permanent officer allowed to retire before having qualified for retired pay may be granted a gratuity provided he has not less than ten years' commissioned service—namely, £1,500 if he has ten but less than fifteen years' commissioned service; £2,500 after fifteen or more than fifteen years'.

Short-service officers will be eligible on passing to the Reserve for gratuities on the following scale : £100 for each of the first two complete years of service, £150 for each of the third and fourth complete years, and £200 for the fifth complete year; that is, for three years' service on the active list £350; for five years' £700.

These gratuities will not be payable to officers granted permanent commissions, but their service on a short-service commission will count towards retired pay.

Further particulars may be obtained on application to the Secretary, Air Ministry (D.M.S.), Adastral House, Kingsway, W.C.2.

INDIAN MEDICAL SERVICE.

IN May, 1928, the Secretary of State for India issued a communiqué announcing the terms on which the Indian Medical Service would in future be constituted. The communiqué was to the effect:

(i) That the I.M.S. constituted on the same broad lines as at present will be retained primarily to meet the needs of the Indian Army, the Local Governments being required to employ a stated number of I.M.S. officers in order to maintain the necessary minimum war reserve and to provide for European medical attendance for European officers of the I.C.S. and their families.

(ii) That the total number of I.M.S. officers required for civil employment is calculated at 302, of which 212 will be Europeans and 90 Indians.

(iii) That there will be 237 posts for these officers after allowing for leave and study reserve, 178 of which will be in the provinces and 59 under the Government of India.

These posts will be filled as follows:

Under Provincial Governments: 178 posts, of which 112 must be held by European officers, the remaining 66 to be open to Europeans or Indians.

Under Government of India: 59 posts, of which 28 will be open to Europeans or Indians, the remaining 31 being open to Europeans only.

(iv) That the medical requirements of European members of the Superior Civil Services are based on data which will change from year to year as the proportion of European to Indian officers gradually diminishes, and will be subject, therefore, to periodical revision.

(v) That certain rules will come into force as an integral portion of the scheme. These rules deal with the question of employment on the military and civil side, and provide *inter alia* that liability to serve on either the military or civil side will be a definite condition of service for all future entrants to the Service.

The civil appointments which are reserved for officers of the I.M.S. are scheduled in the communiqué.

European candidates for admission to the I.M.S. must be British subjects under 32 years of age, and must be registered under the Medical Acts in Great Britain and Northern Ireland. A gratuity of £1,000 on retirement after six years' service, or £2,500 after twelve years' service, together with free return passages, is offered.

* Except for periods of service under Indian administration. For such periods officers receive pay and allowances at rates and subject to conditions authorized from time to time by the Government of India.

† These allowances are issued only when accommodation, fuel and light, rations and personal attendance are not available in kind. Normally provision in kind is available for junior officers. "Married" rates of allowances are payable only to married officers who have reached the age of 30 or the rank of squadron leader. A colonial allowance is granted in certain commands abroad.

The rates and general scheme of allowances are liable to revision as circumstances may require.

The Indian Medical Service offers wide opportunities of medical experience, including clinical, preventive, specialist, and research work. At the beginning of his career an officer is employed on the military side, which has medical charge of the Indian Army. Promotion is on a time scale up to the rank of Lieutenant-Colonel, and by selection to the ranks of Colonel and Major-General. After two years' Indian service an officer may apply for transfer to the civil side, from which appointments are made to Civil Surgeoncies, which are established at the principal civil centres to provide for the medical needs of civil officials and for general medical administrative purposes; to specialist (for example, public health and bacteriological) services; to research posts; and to professorships at the Medical Schools.

The monthly rates of pay for European officers in the Service who have a "non-Asiatic" domicile are as follows:

Rank.	Service in Rank.	Basic Pay.	Overseas Pay.	Year of Total Service.
1	2	3	4	5
		Rs.	Rs.	
Lieutenant		500	150	1st
			150	2nd
			150	3rd
Captain ...	(i) During first 3 years' service as Captain	650	150	4th
			£15	5th
			£15	6th
	(ii) With more than 3 and less than 6½ years' service as Captain	750	£25	7th
			£25	8th
			£25	9th
	(iii) With more than 6 years' service as Captain	850	£25	10th
			£25	11th
			£30	12th
Major ...	(i) During first 3 years' service as Major	950		
	(ii) With more than 3 and less than 6 years' service as Major	1100		
	(iii) With more than 6 years' service as Major	1250		
Lieut.-Col.	(i) Until completion of 23 years' total service	1500	£30	13th and over
	(ii) During 24th and 25th years' total service	1600		
	(iii) After completion of 25 years' total service	1700		
	(iv) When selected for increased pay	1850		

Extras.—In addition to the above rates various allowances are admissible for a large number of special appointments on both the military and the civil side which may be held by members of the Indian Medical Service. Special high rates of pay are also attached to the numerous administrative appointments open to officers in both branches of the Service.

Officers on appointment will receive an outfit allowance of £50.

With the exception of Administrative Officers, military or civil, and officers holding certain special appointments, officers are not debarred from taking private practice, so long as it does not interfere with their proper duties.

The rates of pension are as follows.

	Per annum.
	£
After 17 years' service for pension	400
,, 18 ,, ,, ,, ...	430
,, 19 ,, ,, ,, ...	460
,, 20 ,, ,, ,, ...	500
,, 21 ,, ,, ,, ...	540
,, 22 ,, ,, ,, ...	580
,, 23 ,, ,, ,, ...	620
,, 24 ,, ,, ,, ...	660
,, 25 ,, ,, ,, ...	700
,, 26 ,, ,, ,, ...	750
,, 27 ,, ,, ,, ...	800

These rates are subject to alteration on account of a rise or fall in the cost of living as compared with the year 1919 to an extent not exceeding 20 per cent. in all, the revision being undertaken triennally with effect from July 1st, 1927. A reduction of 4½ per cent. has been made on this account from the amounts shown.

There are additional pensions ranging from £65 to £350 per annum for officers who have held administrative appointments.

An officer on appointment is provided with a free passage to India. The wives and families of officers who are married prior to the date of the officers' embarkation on first appointment will also be provided with free passage to India, subject to the payment of messing charges.

Officers and their families are also eligible for passage concessions under which they are granted a certain number of return passages home at Government expense during their service.

Officers are required to undergo courses of instruction at the Royal Army Medical College, and at Aldershot, lasting approximately six months, prior to their embarkation for India on first appointment.

Further particulars may be obtained from the Under Secretary of State for India, Military Department, India Office, London, S.W.1.

PRISON MEDICAL SERVICE.

CANDIDATES for the prison medical staff are approved by the Secretary of State for the Home Office on the recommendation of the Prison Commissioners. The Chairman of the Board is Mr. A. Maxwell, C.B. Application for employment may be made to the Board on a special form, which can be obtained from the Secretary, Prison Commission, Home Office, London, S.W.1.

In the smaller prisons the medical officer is usually a local practitioner, but in the larger the members of the medical staff are required to devote their whole time to the service. In the case of those required to give their whole time to the service the appointment in the first instance is to the post of medical officer Class II, and from the seniors of this rank the medical officers Class I are selected as vacancies occur.

In February, 1923, the then Home Secretary appointed a committee to report on what changes, if any, should be made in the remuneration or other conditions of service of officers at the prisons and Borstal institutions in England and Scotland and at Broadmoor Criminal Lunatic Asylum. Evidence was given on behalf of the British Medical Association by the Medical Secretary, who pointed out that the salary offered to Class II medical officers—namely, a basic salary of £300 rising by annual increments—was, even when the allowances and bonus were reckoned in, less than the £500 a year the Association looked upon as the minimum commencing salary which should be given to a whole-time medical man holding such a responsible office. Following the report of the committee, which was issued in November, 1923, the salaries of whole-time prison medical officers were increased to: Medical officer Class II, £350, rising by annual increments of £20 to £600; medical officer Class I, £650, rising by annual increments of £25 to £800. Unfurnished quarters are provided, or an allowance in lieu is made. The civil service bonus is paid on the salary. There are 15 medical officers Class II, 12 medical officers Class I, and 23 part-time medical officers.

The service is a small one, and therefore vacancies are comparatively rare and promotion is very slow.

POOR LAW MEDICAL SERVICES.

A NUMBER of whole-time appointments exist under the various Poor Law authorities in Great Britain, certain of which, notably in the metropolis and the chief provincial cities, maintain large well-equipped hospitals organized under purely medical administration. Posts are available to medical practitioners as superintendents and assistant officers in hospitals and infirmaries, and as resident officers in other institutions, such as poorhouses, workhouses, etc. Conditions and salaries show considerable variation; salaries for resident assistant medical officers in Poor Law infirmaries usually range from £200 to £450 a year, with full board, the duties being much the same as, but as a whole more responsible than, those of a house-physician or house-surgeon in a general hospital. Medical superintendents are paid from £600 to £1,600 a year, with house, light, coal, laundry, etc., and in some cases the first assistant is termed deputy medical superintendent and receives £450 to £750 a year, with similar emoluments. This service, therefore, offers openings for young practitioners and the prospect of a reasonable degree of progress for those who may choose to make it their career, with security of tenure, and provision for superannuation. It should be added that the attractiveness or otherwise of any particular post is affected considerably by the policy adopted by the authority under whose jurisdiction it falls. In the more advanced areas there is a high degree of differentiation in treatment between the sick and mentally affected, and the purely pauper class (between the hospital and the workhouse); the tendency in such areas has been to develop the hospital services on lines approximating to those ruling in the voluntary hospitals. In the smaller unions, however, lay control, through the administration by a workhouse master of the whole organization, has been

preserved, and medical appointments in such circumstances are less attractive. A considerable change in administrative conditions in the Poor Law in England and Wales has been effected by the passing of the Local Government Act, 1929, which from April 1st, 1930, abolishes the old boards of guardians, and transfers their functions to the county councils and county borough councils. This should result in greater uniformity in conditions, and probably in a higher degree of specialization in Poor Law work, particularly on the medical side, and a closer assimilation to other public health services. In addition to the full-time appointments of the character mentioned, the Poor Law service offers numerous part-time posts, such as those of district medical officer, parish medical officer, public vaccinator, etc., which are practically all held by general practitioners.

MEDICAL PRACTICE IN BRITISH DOMINIONS AND FOREIGN COUNTRIES.

MEDICAL Acts have now been passed in almost all places forming part of the British Empire beyond the seas, and registers of duly qualified practitioners are consequently maintained. To these registers medical men educated in the United Kingdom are generally admissible merely on payment of a registration fee, providing they produce evidence that they are of good repute and are either registered or eligible for registration in the United Kingdom, as the local requirement may be. The only exception to this statement that need be made relates to the Dominion of Canada. Each of its provinces acts in medical matters as an independent State. The result has been that reciprocity of practice has in the past been established between this country and all the provinces of Canada except British Columbia, where certain obstacles were never overcome. It has, however, to be recorded that reciprocity with Saskatchewan, New Brunswick, Ontario, and Quebec has recently been brought to an end by those provinces. We would advise any medical man proposing to practise in Canada first to communicate with the Provincial Registrar, stating what degrees or diplomas he holds, and asking for information as to the precise steps he must take in order to obtain admission to the Provincial Register. The Licence of the Dominion Council, which can only be obtained after examination, entitles its holder to practise in any of the provinces of Canada, though in regard to Quebec there is a proviso that "he must have been registered in the province five years prior to the application for the recognition of the Dominion Licence." In order to sit for the examination for the Dominion Licence, it is necessary to obtain a licence from one of the provinces, but this can be obtained from one of those with whom reciprocity has been established.

Italy and Japan are the only two foreign States with which complete medical reciprocity has been established, though there are other countries which grant a limited recognition to British qualifications. Generally speaking, in Continental countries (with the exception of the kingdom of Italy) a British medical man desiring to exercise his profession therein must pass practically the same examinations as those imposed on natives of the country. The same observation applies to all foreign States in the South American continent. Each of the United States of North America has its own laws and regulations governing medical practice; and all of them require the holder of a British qualification to submit to an examination. A number of the States, including New York, Illinois, Michigan, and Indiana require naturalization.

A pamphlet showing the conditions under which medical and dental practitioners legally qualified in their own country may practise abroad can be obtained from the office of the General Medical Council, 44, Hallam Street, Portland Place, London, W.1, price 2s. 6d., or 2s. 9d. post free in the United Kingdom. Practitioners who think of going abroad to practise will find therein much useful information, including the name of the official in each country to whom requests for further particulars should be addressed. A new edition was published this year.

MEDICAL APPOINTMENTS IN THE COLONIES AND MANDATED TERRITORIES.

MEDICAL appointments in the self-governing Dominions and the territories under their control, and in Southern Rhodesia and Malta, are made by the Governments concerned, and are not in general open to candidates in the United Kingdom. In Ceylon, Mauritius, Jamaica, Barbados, the Bahamas, and Bermuda vacancies are practically always filled by the appointment of qualified local candidates or, in the case of some of the higher posts, by transfer from other colonies. Appointments to the medical services of the remaining colonies and other territories under the administrative direction of the Colonial Office are made by the Secretary of State for the Colonies in this country. Such appointments are to a given colony or group of colonies, for there is no unified service directly administered from the Colonial Office. It follows that conditions of service and superannuation are in the main determined by the economic resources and general public health policy of the individual colony and its local government, and vary almost as widely as do conditions of climate. Moreover, the extent of the control exercised by the Colonial Office varies according to the constitutional status of the particular colony, and the detailed information available centrally is not always complete. The intending candidate, therefore, should make comprehensive inquiries as to local conditions, and particularly as to facilities for private practice where this is included in the terms of appointment. He will also do well to supplement official information by reference to the Medical Secretary at the Central Office of the British Medical Association (Tavistock Square, London, W.C.1), where reports obtained from time to time from the local Branches are available. This is the more necessary because facilities for transfer from the Medical Service of one colony to that of another are as yet practically non-existent, except in connexion with specialist and senior appointments. This sets strict limits upon the opportunities for promotion.

To those physically and mentally suited to the climatic and social conditions peculiar to the various colonies the Colonial Medical Services should, and in some cases do, offer a field of professional activity rich in interest and in opportunity for pioneer work. The scope for research is wide, and facilities for its prosecution are beginning, however tardily, to be provided. In this connexion a committee was appointed in 1927 whose function it is to advise the Secretary of State and the Medical Research Council upon the initiation and promotion of medical research in the interests of the Colonial Empire; upon the recruitment and conditions of service of the necessary personnel; and upon the management and allocation of any funds available for these purposes. An increased number of specialist posts is becoming available in the larger services, and the general policy is to fill them by promotion of suitably qualified junior officers. The potentialities of sanitation are beginning to be appreciated by local administrations, and the post-war economic stringency to which the delay of essential reform was usually attributed is giving place to more favourable conditions. There are also signs of increasing parliamentary and departmental interest in the development of a sound health policy, amongst which the insertion in this year's Colonial Development Act of a clause specifying the promotion of public health as one of the objects of the measure to be kept prominently in view in connexion with schemes of colonial development is significant. The Act as originally drafted was said to cover this amongst other objects, but it was made clear in the course of debate that the House would not be satisfied without specific reference to public health.

The outlook for the Colonial Medical Service is thus in the main a hopeful one, and especially so in the larger and better organized branches. It is unfortunate that this cannot be said of all of the smaller services. These are in some cases still hampered by conditions which make efficiency unattainable. At the worst they are starved of material resources in the name of economy, understaffed and underpaid, with inadequate facilities for study leave,

and at the mercy of an administration in which the nominal head of the Service has no effective voice. Hence the urgent necessity remains for making careful and sufficient inquiry as to the position in any given Service before accepting appointment.

The medical services recruited in this country by the Secretary of State for the Colonies include those of West Africa, East Africa, Malaya, Hong-Kong, the West Indies, Fiji and the Western Pacific territories, and Palestine, besides a number of smaller services offering individually one or two appointments at an inadequate remuneration and with no prospect of promotion. In addition, certain medical appointments in the service of the Government of Iraq are filled with the concurrence and normally upon the recommendation of the Secretary of State.

In the Fiji Medical Service, although the basic salary of district medical officers (£500, by £25 to £725) is below the £600 minimum recommended as adequate by the British Medical Association, this fact is offset by the concession of allowances of from £175 to £275 in five of the districts, the value of private practice in the remaining seven being estimated at from £100 to £600 a year.

The services in the West Indies and some of the smaller colonies have not yet conceded the £600 minimum commencing salary, and whilst facilities for remunerative private practice, general conditions of service, and a relatively low cost of living must in some instances be taken into consideration, these compensations are by no means universal. The services in the Leeward and Windward Islands are in a condition which requires special notice by way of warning.

In general, candidates for these services must be between the ages of 23 and 35, although these limits are not for the moment absolute. Appointments are, subject to a varying period of probation, for the most part classed as permanent and pensionable, but there are some appointments by agreement for a specified limited term of service. There is no entrance examination, but practitioners selected for appointment must obtain a certificate of physical fitness from one of the consulting physicians to the Colonial Office. Post-graduate experience in hospital appointments is desirable, and in some cases special allowances are conceded to the holders of a D.P.H. Successful candidates are normally required to undergo an approved course of instruction in tropical medicine, the fees for their tuition being defrayed by the Government and an allowance being paid during their instruction. Officers accepting employment under the Government of Iraq are required to enter into an agreement to serve that Government for a definite period of three, five, ten, or fifteen years. These posts are not pensionable, and officers serving for a term longer than three years are required to contribute one-twelfth of their pay to a provident fund, to which the Government of Iraq makes a contribution equal to one-sixth of their pay.

The bulk of the appointments made by the Secretary of State in this country are to the West African Medical Staff, the East African Medical Service, and the Medical Services in Malaya. These are the strongest individual services numerically, and therefore offer more frequent vacancies, better prospects of promotion, and better chances of specialist appointments than the smaller services.

West African Medical Staff.

This is amongst the best organized and best paid of the Colonial Services. The territories covered by the service include Nigeria, the Gold Coast, Sierra Leone, and the Gambia. Climatic conditions vary considerably over this area, but they are in general admittedly trying. This fact is at present recognized by the provision of more frequent leave periods than are usual elsewhere.

The rate of pay for a medical officer is £660 on appointment, rising by annual increments to £960, together with a seniority allowance of £72 a year after reaching £720. There is a considerable number of specialist and administrative posts carrying relatively high salaries, varying from £1,300, with duty allowance of £260, to £1,800, with duty allowance of £360. All appointments in the staff are pensionable. Officers may retire voluntarily on reaching 50 years of age, and may be called upon to retire at 55. Pensions are calculated at the rate of 1/480th of the officer's pensionable emoluments (salary and house allowance) in respect of each complete month of service. Alternatively a gratuity and reduced pension may be granted, if desired, under certain conditions. Gratuities of £1,000 or £1,250 may be drawn on retirement after nine or twelve years' service. Members of the West African Medical Staff are not usually permitted to take their wives or young children to the West Coast until they have acquired experience of the conditions of life and have obtained the sanction of the Governor. In the case of young children this is only exceptionally given.

African Medical Officers.

Membership of the West African Medical Staff is limited to British subjects of European parentage, but a number of Government appointments for African medical officers exist in the West African Colonies. These appointments carry salary on the scale £500–£25–£600, and there is a higher scale £600–£30–£720. In addition, in Nigeria and the Gold Coast, arrangements have been made for the employment of a few young African medical men temporarily on the hospital staffs, with a view to appointment to the Government service later, if suitable. In such cases a salary of £400 a year is paid.

East African Medical Service.

This service includes Kenya, Uganda, Tanganyika Territory, Nyasaland, Zanzibar, and British Somaliland. In East Africa there is very wide scope for clinical work, both medical and surgical, as well as for research and for preventive medicine and sanitation. The service as a whole is fully alive to its responsibilities and opportunities; individual initiative is encouraged, and the career of a medical officer depends, not on seniority alone, but to a large extent on his own capability. As a rule it is preferable that medical officers on first appointment should not be married, although in all but a few stations conditions allow a medical officer's wife to accompany him. The service includes a medical and a sanitary division. The former is open to those holding ordinary medical and surgical qualifications, post-graduate experience in a hospital appointment being an advantage; posts in the sanitary division will as far as possible be filled by those holding a Diploma in Public Health or a Diploma in Tropical Medicine and Hygiene. Climatic conditions vary considerably. In a considerable part of Kenya they approximate more to the temperate than the tropical zone; but there are some areas in the East African Dependencies where conditions more closely resemble those in West Africa. The rate of pay for a medical officer is from £600 on appointment, rising by annual increments of £30 to £840, and thereafter, subject to an efficiency bar at this point, by £40 to £920. Holders of the D.P.H. receive a special concession of two increments on appointment, thus reaching the maximum of the grade two years earlier than they would otherwise do. Private practice may be permitted in certain circumstances, but there is no right to it even in stations where opportunities may exist.

As in the case of the West African Medical Staff, a candidate can only apply for appointment to the East African Medical Service in general and is liable to transfer between the several dependencies, but he may express his preference for any particular colony, and his wishes will, we are informed, be met as far as possible. As a rule, transfer only takes place on promotion or at an officer's own request. The gratuities available on retirement after nine or twelve years' service are similar to those for the West African Medical Staff. Officers may elect or may be required to retire on pension on reaching the age of 50 years. Pensions are calculated at the rate of 1/480th of emoluments (including value of free quarters) for each completed month of service.

Medical Services in Malaya.

These services cover the Straits Settlements, the Federated Malay States, and some of the unfederated States. The commencing salary of 500 dollars a month, *plus* a temporary allowance of 10 per cent. for single and 20 per cent. for married officers, is generally considered adequate. A non-pensionable allowance of 100 dollars a month is paid to officers holding the D.P.H.

The climate of Malaya is, for the tropics, very healthy. It varies little during the year. The mean maximum and minimum temperatures are 86.8° and 74.3° F. In some parts there are no marked rainy and dry seasons, the

rainfall being evenly distributed throughout the year. In others there are a couple of dry months and a couple of exceptionally rainy months in the year. The average rainfall is about 100 inches a year, and vegetation is always green. People who lead regular, active lives have no difficulty in keeping in good health. European children do well in Malaya up to the age of about 6. Numerous hill bungalows are available already for rest and change, and a large Malayan hill station is about to be constructed at a height of over 5,000 feet at Cameron's Plateau, on the Perak-Pahang boundary.

The professional duties of a medical officer may include medical, surgical, medico-legal, and public health work. His administrative work comprises hospital administration, diets, returns, and financial work, and includes the inspection of smaller hospitals and dispensaries. Clerical work is reduced to the smallest possible amount. An endeavour is made to consider an officer's own bent when posting him for duty. Districts vary in size and a certain amount of travelling will be necessary. The white population in each district varies. The district hospitals hold from 50 to 300 beds. There is a staff of locally recruited medical men, mostly trained at the Singapore College of Medicine. Asiatic dressers and trained hospital assistants are employed in hospitals and dispensaries. In addition to European sisters, there is a large local nursing staff. All hospital equipment is supplied by Government, including instruments. At both the Institute for Medical Research in Kuala Lumpur, Federated Malay States, and the King Edward VII College of Medicine, Singapore, there are opportunities for research as well as for routine investigations. Promising officers may be stationed at the Institute for short periods if they can be spared from other duties. In addition to the full-time professional posts at the College of Medicine, several of the medical staff in Singapore hold part-time lectureships.

It may fairly be said that the Malayan Medical Services now offer considerable scope for suitable candidates. There is relatively to other services a large number of special appointments available in surgery, radiology, public health, and pathology, and to those seeking a career in teaching the professorships at the College of Medicine, Singapore, offer an additional attraction.

SUDAN MEDICAL SERVICE.

This service is a department of the Sudan Government, and includes a number of Syrian medical officers and a number of assistant medical officers who are natives of the Sudan. The British medical inspectors are from the outset senior to all other medical officers. The service offers ample opportunities for specialization and for research, as well as for general medical and surgical work.

The climate varies, but is not in general unfavourable, though hot. In the northern desert the nights are cool, even in the summer; in the central there is a rainy season of about four months, during which large areas become malarious. The southern area is more tropical in character, and mosquito-protected houses, nets, and protective quinine are essential during the greater part of the year, though the winter months are cool and pleasant. It is not considered desirable for medical inspectors to be accompanied by their wives until they have gained some knowledge of the language and the general conditions of life.

The commencing pay of a medical inspector is £E.720. On confirmation of appointment and success in the requisite examinations in Arabic the salary is increased by periodic increments to £E.1,200. There are four senior administrative posts carrying higher salaries. There is a compulsory contribution of 5 per cent. of pay towards pension, which, for a medical inspector, amounts, after twenty years' service, to £E.500 a year.

OFFICIAL SOURCES OF INFORMATION.

All inquiries in connexion with medical appointments in the self-governing Dominions and their dependencies should be addressed to the High Commissioners or Agents-General for the Dominions. Intending applicants are also recommended to consult the *Dominions Office and Colonial Office List*, which may be seen at the Colonial Office Library or at the Library of the British Medical Association if not otherwise available, and the Professional Handbook, Part III (price 4d.) issued by the Overseas Settlement Department, Colonial Office, Caxton House, Tothill Street, London, S.W.1.

The position in Egypt is at present uncertain; questions as to the possibility of any medical appointments becoming available under the Egyptian Government should be addressed to the Director-General, Public Health Department, Cairo.

Inquiries as to vacancies and conditions in the Sudan Medical Service should be addressed in the first instance to Dr. Hodson, 24, Welbeck Street, London, W.1.

All inquiries in connexion with Colonial medical appointments made by the Secretary of State for the Colonies, or such vacancies as may occur in Iraq or Palestine, should be addressed to the Private Secretary (Appointments), Colonial Office, 2, Richmond Terrace, Whitehall, London, S.W.1.

There remain a number of medical appointments made by mining companies and other commercial undertakings in various parts of the tropics. Much caution should be exercised in accepting such posts, and the form of contract should be subjected to very careful scrutiny. Advice in this connexion should always be sought from the Medical Secretary of the British Medical Association, British Medical Association House, Tavistock Square, London, W.C.1.

DEGREES FOR PRACTITIONERS.

AT one time it was the almost universal custom for medical students educated in London and aiming at general practice not to seek a university degree, and as that custom still prevails to a considerable extent a large proportion of medical men in England possess diplomas or licences to practise but not degrees in medicine. This is a fact which they sometimes find reason to regret, and to such practitioners the following paragraphs may be of interest. It should be noted that the M.D.Brux. diploma, if obtained subsequently to June, 1886, is not registrable, and that the University of Brussels no longer holds special examinations for foreign medical practitioners.

UNIVERSITY OF DURHAM.

The degree of M.D. is granted by the University of Durham to registered practitioners of not less than fifteen years' standing, who have been qualified and in practice for that period, upon the following conditions, *without residence*: The candidate must be 40 years of age, and must produce a certificate of moral character from three registered medical practitioners. Should he not have passed an examination in arts previous to the professional examination in virtue of which his name was placed on the *Register*, he is examined in classics and mathematics: if otherwise, he is required to translate into English passages from any one of the following Latin authors: Caesar, *De Bello Gallico* (first three books); Virgil, *Aeneid* (first three books); or Celsus (first three books). Natives of India or the British Colonies are placed on the same footing as natives of Great Britain, and must be registered on the books of the General Medical Council of the United Kingdom.

Professional Examination.—The candidate must pass an examination in the following subjects: (i) Principles and practice of medicine, including psychological medicine, hygiene, and therapeutics; (ii) principles and practice of surgery; (iii) midwifery and diseases of women and children; (iv) pathology, medical and surgical; (v) anatomy, medical and surgical; (vi) medical jurisprudence and toxicology. Candidates are examined by means of written papers, clinically, and viva voce at the College of Medicine, Northumberland Road, Newcastle, and in the Royal Victoria Infirmary. The classical part of the examination may be taken separately from the professional on payment of a portion (£10 10s.) of the full fee.

The examinations are held twice a year, in June and December. Notice, accompanied by the fee and certificates, must be sent to the Secretary of Examinations, at the University of Durham College of Medicine, Newcastle-on-Tyne, at least twenty-eight days before the commencement of the examination.

Fees.—The inclusive fee for both professional and classical parts of the examination, together with the degree fee, is 50 guineas; if a candidate fail to pass, 20 guineas are retained, but if he present himself again 40 guineas only are required.

THE SWISS UNIVERSITIES.

The Universities of Lausanne and Bern have arrangements which permit British practitioners to proceed to the M.D. degree, but this alone does not confer the right to practise in Switzerland, for which the possession of the State or Federal Diploma is necessary. Neither degree nor diploma is registrable in this country.

At Lausanne the British practitioner has to produce (1) a certificate of matriculation in a British university, or of having passed a preliminary examination recognized by the General Medical Council for the purposes of registration as a medical student; (2) a certificate of a degree or diploma qualifying for practice in the United Kingdom and the certificate of registration as a medical practitioner in the United Kingdom. He must then undergo a viva voce examination in three subjects of the final medical examination. Next he must present a thesis for the doctorate, prepared and completed in one of the Lausanne clinics under the direction of one of the professors of the Faculty of Medicine. Residence for a semester (October to March or April to July) is obligatory. The fees are: on matriculation 20 francs; on inscription for the viva voce examination 50 francs; on presentation of thesis 200 francs; for diploma and graduation 25 francs; for courses of lectures and laboratory instruction 80 francs; the printing of the thesis costs from £7 to £12. Applications for admission should be made to the Dean of the Medical Faculty, l'ecole de Médecine, Place de l'Ours, Lausanne. Dr. C. A. H. Franklin (56, Southborough Road, Bickley, Kent), honorary secretary of the Lausanne Medical Graduates, will supply further information.

SPECIAL DIPLOMAS.

INFORMATION about the regulations for the various Diplomas in Tropical Medicine, in Psychological Medicine, and in Public Health is given in the appropriate sections of this Educational Number at pp. 424, 425, 427. Further details in regard to the D.P.H. and the D.T.M. will be found in *Dr. Andrew Balfour's Guide to the Regulations, Courses, and Examinations for Qualifications in Public Health and Tropical Medicine*, published by the British Medical Association, Tavistock Square, W.C.1, at the price of 3s.

It should perhaps be noted here that of the various diplomas in special subjects granted by licensing bodies only those in Public Health and Sanitary Science and State Medicine are at present admissible for entry in the official *Medical Register*, though other special diplomas may, of course, be included among the particulars of qualifications set out in the *Medical Directory*.

As stated at page 398, a Diploma in Tuberculous Diseases is granted by the University of Wales to qualified medical practitioners: new regulations for this diploma will come into force in 1930.

DIPLOMAS IN MEDICAL RADIOLOGY.

Diplomas in Medical Radiology are granted by the Universities of Cambridge, Edinburgh, and Liverpool.

The Cambridge Diploma.—A Diploma in Medical Radiology and Electrology is granted by the University of Cambridge. The primary object is to provide adequate training in a branch of medical work which is becoming increasingly important and difficult, and which is outside the ordinary medical curriculum. The diploma is open only to those who hold a medical qualification approved by the Diploma Committee. Under the new regulations, which came into operation in October, 1928, the course has been extended from six to nine months. The first three months (October to December), which may be spent either in Cambridge or in London, are occupied with lectures and practical work in physics and electrotechnics, together with an introductory course in medical radiology and electrology. The work for the second three months (January to March) can be done in London only, and comprises lectures and clinical instruction in radiology and electrology given by lecturers appointed by the Educational Committee of the British Institute of Radiology, together with clinical experience in the radiological department of a hospital recognized for that purpose by the Diploma Committee. During the last three months a candidate is required to hold a clinical clerkship, or other similar appointment, in the radiological department of a recognized hospital. Hospitals at a number of provincial centres, as well as in London, have been recognized by the Committee for this purpose. In exceptional circumstances exemption from this regulation may be granted by the Committee. The examination for Part I (physics and electrotechnics) is normally taken at the end of the first three months, and the examination for Part II at the end of six months. At the conclusion of the nine months' course a candidate is required to present a thesis composed by himself. This thesis is to be in the form of a critical report, with notes upon six cases, either in radiology or electrology or in both these subjects, and must illustrate various methods of diagnosis or treatment. The course for 1929–30 begins on October 1st. Examinations for Part I will begin on January 8th and April 14th, 1930, and for Part II on April 15th and July 16th, 1930. Further particulars of the courses and examinations can be obtained from the Secretary for the Diploma, G. Stead, M.A., Cavendish Laboratory, Cambridge, or from Dr. A. E. Barclay, Radiological Department, Medical Schools, Cambridge, or from the Director, British Institute of Radiology, 32, Welbeck Street, London, W.1.

The Edinburgh Diploma.—Candidates for the diploma must be graduates in medicine and surgery of the University of Edinburgh, or hold corresponding registrable degrees or qualification from some other licensing body. Candidates are not admitted to the examination for the diploma until after the lapse of not less than one year from obtaining a registrable qualification, which qualification must be registered before admission to the examination. The course of study begins in October and extends over a period of not less than three terms. The examination, which is written, oral, and practical, is in two parts: (*a*) physics, and (*b*) radiology. The examination is held twice yearly—namely, July and October. Full particulars may be obtained from the Dean of the Faculty of Medicine. In this connexion it may be noted that radiology can now be taken as the special subject in the examination for Membership of the Royal College of Physicians of Edinburgh. Several candidates have already taken radiology as their special subject; it means that an honours standard has to be attained.

The Liverpool Diploma.—The University of Liverpool grants a Diploma in Medical Radiology and Electrology. Candidates before admission to the examination for the diploma must possess a registrable qualification approved by the university in medicine and surgery, and must have attended courses of instruction in (*a*) physics (two terms); (*b*) (i) radiology and (ii) electrology, during the six months in the *x*-ray and electro-therapeutic departments of a hospital or hospitals. An examination is held in March each year, the subjects being (*a*) physics, (*b*) radiology and electrology. Examination in either part may be taken separately. Fees: tuition, £24 5s.; examination and diploma, £6 5s. These courses commence during the first week in October. Application should be made to the Dean, Faculty of Medicine, the University of Liverpool.

DIPLOMA IN LARYNGOLOGY AND OTOLOGY.

The Conjoint Examining Board in England (Examination Hall, Queen Square, London, W.C.1) grants a Diploma in Laryngology and Otology (D.L.O.) after an examination held in June and December. The examination comprises two parts: Part I, on the anatomy, embryology, and physiology of the ear, nose, pharynx, larynx, trachea and bronchi, and oesophagus; Part II, on the recognition and use of special instruments and appliances, and the medicine, surgery, and pathology of these regions. Candidates may enter for Part I at any time after a registrable qualification in medicine, surgery, and midwifery has been obtained. Candidates may enter for Part II on completion of one year of special study of diseases of the ear, nose, pharynx, and larynx, after a registrable qualification has been obtained, provided that Part I has been previously passed, and on production of certain certificates. The conditions of study may be modified at the discretion of the Committee of Management in special cases. The fee for admission or readmission to each part is six guineas.

DIPLOMA IN OPHTHALMIC MEDICINE AND SURGERY.

A special Diploma in Ophthalmic Medicine and Surgery is granted by the University of Oxford and by the Conjoint Examining Board in England.

University of Oxford.—For the Diploma in Ophthalmology (D.O) attendance on a twelve months' course of

clinical ophthalmology in hospitals or institutions recognized for the purpose by the Board of the Faculty of Medicine, and on a course of instruction in Oxford lasting two months, is obligatory. Candidates must have their names on the *Medical Register* of the United Kingdom, unless, being Bachelors or Doctors of Medicine of universities outside the United Kingdom, they have obtained special permission from the Board of the Faculty of Medicine.

The Conjoint Board.—The Diploma in Ophthalmic Medicine and Surgery of the Conjoint Examining Board of the Royal College of Physicians of London and Royal College of Surgeons of England is issued after completion of an examination held in two parts—in January and July. The examination in each case is partly written, partly oral, partly clinical or practical. Part I comprises anatomy and embryology of the visual apparatus, physiology of vision, elementary optics; Part II comprises optical defects of the eye, ophthalmic medicine and surgery, pathology with special reference to medical and surgical ophthalmology. Candidates may enter for Part I at any time after a registrable qualification in medicine, surgery, and midwifery has been obtained. Candidates may enter for Part II on completion of one year of special study of ophthalmology after a registrable qualification has been obtained, provided that Part I has been previously passed, and on production of certain certificates. The conditions of study may be modified at the discretion of the Committee of Management in special cases. The fee for admission or readmission to each part is six guineas.

MEDICAL MISSIONARIES.

MISSIONARY societies are in constant need of qualified men and women to fill vacancies as they occur in their hospitals, and also to enable them to take advantage of fresh openings. To those suitably endowed the mission field offers unique opportunities for interesting work, and the development of native medical schools, as training institutions in connexion with some of the larger mission hospitals, affords excellent scope for valuable work to medical men and women who are qualified to teach. It is not usually expected that medical missionaries should take a position such as would otherwise be occupied by an ordained clergyman or minister, but it is essential that they should be prepared to exert their influence in any hospital to which they may be sent so that a Christian atmosphere may be maintained and the work of evangelization be carried on through the ministry of healing.

As for scientific and other qualifications for the work, medical missionaries, in addition to being physically capable of sustaining a life which makes a great demand upon their strength, should be thoroughly well-trained physicians and surgeons. It is very desirable that they should have held a resident appointment at a general hospital, and have a good knowledge of practical surgery, gynaecology, tropical medicine, and the treatment of eye diseases. Useful information can be obtained from the secretaries of the various Missionary Societies, or from Thomas B. Adam, Honorary Secretary, Medical Advisory Board on Medical Missions to the Conference of Missionary Societies in Great Britain and Ireland, The Crossways, 45, Kenton Road, Harrow, Middlesex, or 19, Furnival Street, E.C.4.

Dental Surgery.

UNTIL the passing of the Dentists Act, 1921, the profession of dentistry in this country was regulated by enactments corresponding very closely with those relating to the practice of medicine—that is to say, there was no direct prohibition of the act of practice; and the Dentists Act of 1878 gave the same degree of protection to legally qualified and registered dentists as was accorded to registered medical practitioners—namely, the reservation of the use of certain titles. This Act provided also (1) that no person should take or use the name or title of "dentist" (either alone or in combination with any other word or words) or of "dental practitioner," or any other name, title, or description expressed in words or by letters implying that he was specially qualified to practise dentistry, unless he was registered, under a penalty of £20; and (2) that an unregistered person could not recover any fee or charge in respect of any dental operation, attendance, or advice. But, in the case of the practice of medicine by unqualified and unregistered persons, certain deterrent factors came into play—such as the inability to give a death certificate—and these did not operate to the same extent in the case of dentistry: hence, unqualified practice was far more prevalent in dentistry than in medicine, and increased after a decision of the House of Lords placing a narrow interpretation upon the words "specially qualified to practise dentistry," by defining the word "qualified" as not referring to competence but to the possession of a recognized diploma.

THE DENTISTS ACT, 1921.

This unsatisfactory position was remedied by the passing into law of the Dentists Act, 1921; its provisions are based largely on the recommendations of a departmental committee appointed in 1917 by the Privy Council "to investigate the extent and gravity of the evils connected with the practice of dentistry and dental surgery by persons not qualified under the Dentists Act." Since November 30th, 1922, no person has been permitted by law to practise or hold himself out, whether directly or by implication, as practising or as being prepared to practise dentistry unless he is on the *Dentists Register* provided for by the Dentists Act, 1878. The practice of dentistry is defined as including "the performance of any such operation and the giving of any such treatment, advice, or attendance, as is usually performed or given by dentists," and the performing of any operation or the giving of any "treatment, advice, or attendance on or to any person as preparatory to or for the purpose of or in connexion with the fitting, insertion, or fixing of artificial teeth." The maximum penalty incurred by an unregistered dentist is £100 for each offence. There are, however, certain important exceptions to the requirement of registration. A registered medical practitioner may practise dentistry without being on the *Dentists Register*, and a registered pharmaceutical chemist or chemist and druggist may extract a tooth where the case is urgent and where no doctor or dentist is available, but the operation must be performed without any kind of anaesthetic; further, any person may carry out minor dental work in a public dental service under the personal supervision of a registered dentist provided it is in accordance with conditions approved by the Minister of Health after consultation with the Dental Board.

Certain persons other than those qualified by examination were entitled to be registered under the new Act. They had to be of good personal character and 23 years of age before July 28th, 1921 (the commencement of the Act), and to have been engaged for five of the seven years preceding that date as their principal means of livelihood in the practice of dentistry in the British Isles, or have been admitted to membership of the Incorporated Dental Society not less than one year before the commencement of the Act. The passing of "the prescribed examination in dentistry" within two years of the commencement of the Act was considered as equivalent to practising for five years, and a registered pharmaceutical chemist or a chemist and druggist who immediately before the commencement of the Act had a substantial practice as a dentist, including all dental operations, was treated as though he had practised for five years. A dental mechanic who for the five years had been carrying on his work as such and has secured the entry of his name on the list of candidates for examination can be registered, provided within ten years of the commencement of the Act he passes the prescribed examination. The Board, however, has no power now to consider any further applications under this Act.

Dentistry may be carried on by a corporate body provided the majority of the directors and all the operating staff are registered dentists, and that no business other than dentistry or only some business ancillary to dentistry is carried on by the company. Companies carrying on the business of dentistry at the present time are permitted to continue to do so with certain restrictions, provided that the name of the company as well as the names of the directors have been entered in a list kept by the Registrar for that purpose. Every director or manager of a company convicted of an offence under the Act will be held to be guilty of the offence unless he proves that the offence was committed without his knowledge, and the court may, in addition to a fine, order that the name of any director convicted shall be removed from the list of directors aforesaid.

A subsequent Act passed in 1923 made provision for the registration of persons who were 21 in November, 1921, who had served during the late war in His Majesty's Forces, and were on that

date engaged as their principal means of livelihood in the practice of dentistry in the British Isles. The Board, however, has no power now to consider any further applications under this Act.

The Dental Board.

On the establishment of the Dental Board in 1921 certain powers and duties of the General Medical Council were transferred to it, including the duty of erasing from the *Dentists Register* any entry which has been incorrectly or fraudulently made. An inquiry into the case of a person alleged to be liable to have his name erased from the *Register* is made by the Board, which reports its findings to the General Medical Council, the order directing the erasure being made by the Council. A name erased from the *Register* can only be restored by the Council upon a report made by the Board. An appeal to the High Court may be made by any person aggrieved either by refusal of the Board to register his name or by the removal of his name from the *Register*. The administrative expenses of the Board are defrayed from the registration fees and annual retention fees, but any surplus may be allocated to purposes connected with dental education and research or to any public purpose connected with dentistry. The office of the Dental Board is at 44, Hallam Street, London, W.1.

Dental Education and Examination.

The preliminary examination in arts is the same for medical and dental students, and the early stages of their education embrace much the same subjects[1]; and, as the dental student is required to obtain a knowledge of the broad principles of medicine and surgery, it is necessary for him to pursue some portion of his studies at a medical school as well as at a special dental school, the latter not undertaking the teaching of these subjects. Registration as a dental student is not in all cases compulsory, though it is to be advised as convenient as affording proof of the commencement of professional education, and it is required by most of the licensing bodies, all of whom insist upon a curriculum covering four academic years.

Degrees in dentistry are granted by the Universities of Bristol, Dublin, Durham, Leeds, Liverpool, London, Sheffield, Queen's University, Belfast, and the National University of Ireland, as will be found stated in the articles on these universities. Licences in dentistry entitling the holder to be registered on the *Dentists Register* are granted by the Universities of Birmingham, Bristol, Durham, Leeds, and Belfast, and by the Royal Colleges of Surgeons of England, of Edinburgh, and of Ireland, and by the Royal Faculty of Physicians and Surgeons of Glasgow.

Recognized dental schools are numerous. In London there are those connected with the Royal Dental Hospital, Leicester Square; the National Dental Hospital (now the University College Hospital Dental School), Great Portland Street; Guy's Hospital; King's College Hospital; and the London Hospital. In the provinces there are the Birmingham Dental Hospital; the Royal Infirmary and the General Hospital, Bristol; the Dental Hospital, and the Public Dispensary, Leeds; the Dental Hospital, Liverpool; the Dental Hospital, Manchester; the Dental Hospital and School, Newcastle-on-Tyne; the Royal Hospital, Sheffield. In Scotland there are the Dental Hospital, Dundee; the Incorporated Dental Hospital and School, Edinburgh; and the Incorporated Dental Hospital, Glasgow; and in Ireland, the Incorporated Dental Hospital of Ireland and the Royal College of Surgeons in Ireland.

All who think of becoming dentists may be advised to study a Memorandum, lately drawn up for their guidance by the Registrar of the Dental Board, setting out in convenient form and in untechnical language information for which request is frequently made to the Board.[2] It will be seen from this pamphlet that in order to assist suitable students the Dental Board has instituted a system of bursaries to pay the fees of those who have not the financial means to qualify, and in some cases maintenance is given as well.

Recommendations of the General Medical Council.

The Dentists Act still leaves to the General Medical Council the duty of controlling the course of study and examinations required for dental qualifications.

The following recommendations as to the course of study and examinations to be required of candidates for degrees or licences in dentistry or dental surgery were adopted by the Council on May 27th, 1922.

Preliminary Examination and Registration.

1. That every dental student shall, at the commencement of his studentship, be registered in the manner and under the conditions prescribed for medical students.

2. That before registration in the *Dental Students Register* every applicant shall be required to have passed, in addition to the examination in general education, which shall be the same as that required for medical students, an examination in Elementary Physics and Elementary Chemistry, conducted or recognized by one of the licensing bodies, which shall also be the same as that required for medical students.

3. That before registration as a dental student every applicant shall produce evidence that he has attained the age of 17 years.

Professional Study.

4. That every candidate for a degree or licence in dentistry or dental surgery shall be required before admission to the final or qualifying examination to produce certificates showing:

(i) That he is at least 21 years of age.

(ii) That he has been registered as a dental student.

(iii) That he has, subsequently to the date of registration as a dental student, been engaged in professional study for at least four years, of which three years at least shall be spent at a school or schools recognized for professional study by one of the licensing bodies.

(iv) That, subsequently to the date of registration as a dental student, he has attended at a recognized medical school courses of instruction, which shall be the same as those required for medical students, in the following subjects: (*a*) Chemistry, and (*b*) Physics, in their application to medicine; (*c*) Elementary Biology. That he has attended at a recognized medical school courses of instruction in the following subjects: (*d*) Human Anatomy (with dissections and demonstrations) for three academic terms. (*e*) Physiology (with laboratory instruction, including Practical Histology) for two academic terms; (*f*) General Pathology (including Bacteriology) for two academic terms; (*g*) Medicine for two academic terms; (*h*) Surgery for two academic terms; (*i*) the practice of a recognized general hospital or hospitals of not less than eighty beds, with certified instruction in Clinical Medicine and Clinical Surgery, for four academic terms.

(v) That he has attended at a recognized dental school courses of instruction in the following special subjects: (*a*) Dental Anatomy and Physiology, human and comparative. The course should comprise a minimum of twenty meetings of the class. (*b*) Practical Dental Histology and Morbid Histology. The course should comprise a minimum of sixteen meetings of the class. (*c*) Dental Pathology and Surgery. The course should comprise a minimum of twenty meetings of the class. (*d*) Dental Materia Medica and Therapeutics. The course should comprise a minimum of sixteen meetings of the class. (*e*) Dental Metallurgy (with practical work and demonstrations). The course should comprise a minimum of twenty meetings of the class. (*f*) Dental Mechanics (with practical work and demonstrations). The course should comprise a minimum of twenty meetings and twenty demonstrations. (*g*) A course of instruction in the use of Anaesthetics, general and local, employed in dental practice. (*h*) A course of instruction in Radiology as applied to dentistry.

(vi) That he has for at least twenty-four calendar months attended, during the ordinary academic terms, the practice of a recognized dental hospital or of the recognized dental department of a general hospital.

(vii) That he has received for not less than twenty-four calendar months, or for 2,000 hours, practical instruction in dental mechanics.

Professional Examinations.

5. That the examination for a degree or licence in dentistry or dental surgery shall be partly written, partly oral, and partly practical, and shall include the following subjects: (*a*) [illegible] and Biology, in their bearing on Medicine and [illegible]atomy and Physiology. (*c*) General Pathology [illegible] (*d*) Medicine and Surgery. (*e*) Dental Anatomy [illegible] Pathology, Dental Surgery (including Orthodontics), Medica and Therapeutics, and Dental Mechanics and Dental Metallurgy. (*f*) Practical Examination in Dental Surgery. (*g*) Practical Examination in Dental Mechanics and Metallurgy. (*h*) Anaesthetics, general and local, employed in dental practice.

6. That the prescribed subjects of examination may be combined or distributed at the discretion of the licensing bodies, and may be taken at two or more successive stages during the course of professional study; provided that no candidate shall be admitted to any final examination in dental surgery and dental mechanics until he shall have completed the required four years' course of study.

ACKNOWLEDGEMENT.

The detailed information published in this Educational Number of the *British Medical Journal* for the benefit of intending students of medicine and newly qualified practitioners has been revised throughout with the co-operation of the deans and secretaries of the medical schools and kindred institutions and of officials in the several public services, to all of whom we wish to acknowledge our indebtedness.

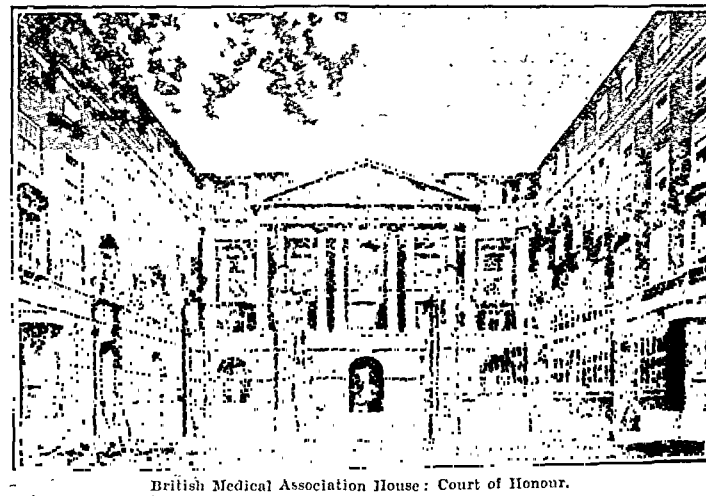
MEMBERSHIP of the Guild of St. Luke is open to all students and practitioners of medicine—both men and women—who are members of the Church of England, the clergy of which are eligible as clerical associates. The Guild was started in London, by a few medical students, over sixty years ago, and there are also now in London a Women's Ward and a Students' Branch, as well as a Midland Counties Ward and a Cambridge Ward. The Chapter of the Guild meets in each month of the academic year, and a festival service is held annually at St. Luke's tide, either at St. Paul's or Westminster Abbey. This year the service will be at the Abbey. Particulars of the objects and activities of the Guild and forms of application for membership can be obtained from the Secretary of the Guild of St. Luke, King's College, Strand, W.C.2.

[*The present issue being the Annual Educational Number, much current material is held over, and neither the "Supplement," nor the "Epitome of Current Medical Literature" is published this week.*]

The British Medical Association:

ITS AIMS, WORK, AND CONSTITUTION.

THE British Medical Association, as stated in our introductory article on the Profession of Medicine, was founded in 1832 to promote the medical and allied sciences, to maintain the honour and interests of the profession, and to foster a feeling of friendship among its members. To attain these objects it holds periodical meetings for the discussion both of medical and scientific subjects and of professional affairs; it publishes the *British Medical Journal*; it maintains a reference and lending library; it has instituted lectures, and scholarships and grants for research. It thus concerns itself with every side of medical work—science, clinical medicine, public health, and the material interests of professional life. The British Medical Association, with a membership now of nearly 35,000, is the oldest, largest, and most powerful British organization devoted to the welfare of the medical profession. It has recently acquired a fine building in Tavistock Square, London, for its headquarters, providing ample accommodation for immediate needs and space for future developments. These premises, designed by Sir Edwin Lutyens, R.A., were formally opened in 1925 by His Majesty the King, Patron of the Association; and the beautiful wrought-iron gates erected as a memorial to the 574 members who fell in the war, by which the main quadrangle is completed, were dedicated on that occasion by the Archbishop of Canterbury. The need for larger accommodation had become insistent owing to the remarkable growth in the central work of the Association during recent years, which had far outstripped the capacity of the premises in the Strand. Further extensions to the building in Tavistock Square are now in progress.



British Medical Association House: Court of Honour.

Constitution and Administration.

The Association has Branches and Divisions throughout Great Britain and Ireland, and also in the Dominions, Colonies, and Dependencies. The Divisions are arranged territorially, and number, in all, 351. For certain purposes of administration or of scientific and clinical work, the Divisions are combined into 96 Branches. Members of Divisions elect representatives on the Branch Councils and also a member or members of the Representative Body, which is the governing body of the Association and determines its policy.

The Council is the executive of the Association. It is elected partly by the Divisions and Branches and partly by the Representative Body, and includes representatives of the Navy, Air Force, Army, and Indian Medical Services elected by the Representative Body. The Representative Body and Council elect standing committees to take charge of different subjects. Among these may be mentioned the Science, Medico-Political, Ethical, Hospitals, Public Health, and Naval and Military Committees. There are Committees also for the Dominions, Scotland, Ireland, and Wales; and for the working machinery of the Association, such as the Organization, Finance, and Journal Committees. The Insurance Acts Committee, elected partly by the Association and partly by insurance medical practitioners, is financed by the Association; it is the recognized executive and mouthpiece of the insurance practitioners of Great Britain.

Privileges of Members.

A member of the Association has the right—

1. To attend the annual and other general meetings of the Association and the meetings of the Division and Branch to which he or she belongs.
2. To take part by personal vote (or in some Divisions by voting paper) in the election of the representative of his or her Division in the Representative Body, and also in the election of members of the Council.
3. To receive by post the *British Medical Journal*, published weekly, which gives a full record, with commentary, of progress in clinical and scientific medicine and of medico-political affairs throughout the British Empire.
4. To receive the help and advice of the central office in any professional difficulty.
5. To use the Library as a reading room, and to borrow current medical or scientific books on payment of postage. Besides modern works and periodical medical literature—foreign as well as English—the library contains many books of historic interest.

The full benefits of the Association can only be secured by the co-operation of large numbers of the medical profession; for the greater the membership and the funds the more efficient and influential the organization. The Association during the past ninety-seven years has been the direct means of benefiting every class of medical men and medical women. In asking for new members it looks not only to the older practitioners but also and especially to those recently qualified. To these a generous concession is made as regards subscription, and there is a special claim to their recognition of the work of the Association in improving the conditions under which they may hold appointments in the public services or in civil life. The Association's work for the Services is well known. It feels a special responsibility towards those members of the profession who by reason of their position are precluded from taking common action, and recent events have proved again its capacity to further their interests.

Subscriptions and Applications for Membership.

The ordinary subscription to the British Medical Association is 3 guineas a year for members resident in the British Isles, but this is subject to various exceptions. Thus, newly qualified practitioners elected within two years of registration pay half this sum up to the end of the fourth year after registration; medical officers on the active list of the R.N., R.A.F., R.A.M.C. (Regular), and I.M.S. pay 2 guineas; concessions are made also to members (in the British Isles) of forty years' standing, to members of ten years' standing who have retired from practice, to medical married couples residing together, and to whole-time teachers and research workers. The ordinary subscription for members living abroad is 1½ guineas, but some Branches have special local subscriptions. A member elected after June 30th pays half the subscription for that year.

All duly qualified British medical practitioners are eligible for election. Full particulars can be obtained from the Medical Secretary, British Medical Association House, Tavistock Square, London, W.C.1; the Scottish Medical Secretary, 7, Drumsheugh Gardens, Edinburgh; or the Irish Medical Secretary, 16, South Frederick Street, Dublin.

ST. ANDREW'S HOSPITAL
FOR MENTAL DISORDERS,
NORTHAMPTON

FOR THE UPPER AND MIDDLE CLASSES ONLY.

President: THE MOST HON. THE MARQUESS OF EXETER, C.M.G., A.D.C.

Medical Superintendent: DANIEL F. RAMBAUT, M.A., M.D.

This registered Hospital is situated in 120 acres of park and pleasure grounds. Voluntary Boarders, persons suffering from incipient nervous and mental disorders, as well as certified patients of both sexes, are received for treatment. Careful clinical, biochemical, bacteriological, and pathological examinations. Private rooms with special nurses, male or female, in the Hospital or in one of the numerous villas in the grounds of the various branches can be provided.

WANTAGE HOUSE.

This is a Reception Hospital in detached grounds, with a separate entrance, to which patients and voluntary boarders can be admitted. It is equipped with all the apparatus for the most modern treatment of Mental and Nervous Disorders. It contains special departments for hydrotherapy by various methods, including Turkish and Russian baths, the prolonged immersion bath, Vichy Douche, Scotch Douche, Electrical baths, Plombières treatment, etc. There is an Operating Theatre, a Dental Surgery, an X-ray Room, an Ultra-violet Apparatus, and a Department for Diathermy and High Frequency treatment. It also contains Laboratories for biochemical, bacteriological, and pathological research.

MOULTON PARK.

Two miles from the Main Hospital there are several branch establishments and villas situated in a park and farm of 650 acres. Milk, meat, fruit, an [illegible] to the Hospital from the farm, gardens, and orchards of Moulton is a feature of this branch, and patients are given every facility in farming, gardening, and fruit-growing.

BRYN-Y-NEUADD HALL.

The Seaside house of St. Andrew's Hospital is beautifully situated in a Park of 330 acres, at Llanfairfechan, amidst the finest scenery in North Wales. On the North-West side of the Estate a mile of sea coast forms the boundary. Voluntary Boarders or Patients may visit this branch for a short seaside change or for longer periods. The Hospital has its own private bathing house on the seashore. There is trout-fishing in the park.

At all the branches of the Hospital there are cricket grounds, football and hockey grounds, lawn tennis courts (grass and hard courts), croquet grounds, golf courses, and bowling greens. Ladies and gentlemen have their own gardens, and facilities are provided for handicrafts, such as carpentry, etc.

For terms and further particulars apply to the Medical Superintendent (Telephone No. 56. Northampton), who can be seen in London by appointment.

THE COPPICE, NOTTINGHAM.
HOSPITAL FOR MENTAL DISEASES.

This Institution is exclusively for the reception of a limited number of Private Patients of both sexes of the Upper and Middle Classes at moderate rates of payment. It is beautifully situated in its own grounds on an eminence a short distance from Nottingham, and from its singularly healthy position and comfortable arrangements affords every facility for the relief and cure of those mentally afflicted. Voluntary Boarders received without Certificates.

For terms, etc., apply to the Medical Superintendent.

HARROGATE CORPORATION

F. J. C. BROOME,
General Manager of Wells and Baths.

The Royal Baths,
HARROGATE.
August, 1929.

Dear Sir,

An Invitation to Visit Harrogate

We are constantly advertising that Harrogate is a BRITISH Spa offering a "Cure" and a Holiday unsurpassed at any Foreign Resort, but unfortunately, advertising not being altogether free from exaggeration, our claims may leave you unconvinced.

To prove our point and to gain your goodwill for a BRITISH Spa we ask you to pay Harrogate a visit to satisfy yourself as to what we are doing and how we do it!

If you will send a postcard, a list of the concessions we ask you to accept during your stay, and Medical and "Lay" Literature, etc., will be sent you by return of post.

I am,
Yours truly,
F. J. C. BROOME,
Spa Manager.

ST. MARY'S HOSPITAL MEDICAL SCHOOL,

W.2.

(University of London.)

The WINTER SESSION will begin on TUESDAY, OCTOBER 1st, 1929.

The Annual Dinner of Past and Present Students will be held on Friday, October 4th, at the Trocadero Restaurant, Sir JOHN F. H. BROADBENT, Bart., in the chair.

EXCEPTIONAL SITUATION.	The Hospital is adjacent to a large poor district on the one side, and near to Kensington Gardens and one of the best residential districts in London on the other side, thus providing for the Student the unusual possibility of living in close touch with his work.
ATHLETIC GROUND.	A new Ground (10 acres) is now in use at Wembley, and can be reached in 20 minutes from the Hospital. A pavilion has been erected at a cost of £3,000.
COMPLETE CURRICULUM.	The entire Curriculum is provided for Medical Degrees and Diplomas, and Students may join the School at once on passing a Preliminary Examination in Arts.
SPECIAL CLINICAL FACILITIES.	The formation of Clinical Units and the affiliation of other hospitals for teaching purposes have largely extended the scope of the clinical teaching. 1,000 beds are now available for the clinical instruction of Students. Special arrangements have been made for the instruction of Students in Venereal Diseases at the London Lock Hospital, and all Students attend a short course at Queen Charlotte's Maternity Hospital. Structural alterations during the past year have provided 2 new Operating Theatres, and 60 additional beds.
INSTITUTE OF PATHOLOGY.	The Institute of Pathology and Research is under the personal direction of Sir Almroth Wright, F.R.S., and includes seven departments. Students receive special training in Pathology, Bacteriology, and Chemical Pathology by means of clerkships in these subjects tenable for a period of 3 months, 72 of these posts being available in each year.
ENTRANCE SCHOLARSHIPS.	Two Entrance Scholarships of £210 each are awarded by nomination in July annually. The Geraldine Harmsworth Scholarship (£200) and other University Scholarships are awarded by nomination in July annually. The Palmer Scholarship (£25 per annum for two years) is awarded in alternate years.
RESEARCH SCHOLARSHIPS.	*Research Scholarships of the value of £200 per annum each* are awarded annually for the purpose of enabling newly qualified students to undertake research under the Director of one of the departments included in the Institute of Pathology.
APPOINTMENTS AFTER QUALIFICATION.	Numerous appointments are open to newly qualified members of the Medical School. Six House Physicians (6 months), Eight House Surgeons (6 months), and Four Resident Obstetric Officers (6 months), are appointed annually. Two Resident Anæsthetists (6 months), £150 per annum, Four Casualty House Surgeons (6 months), £100 per annum, with board and residence. Medical Registrar and Surgical Registrar £200 per annum, with partial board. In addition to the above, Five Assistants to the Medical and Surgical units are appointed from time to time, with salaries ranging from £400 to £750 p.a.

C. M. WILSON (*M.C.*), M.D., F.R.C.P., Dean.

The Illustrated Prospectus of the Medical School may be obtained on application to the Secretary.

CENTRAL LONDON OPHTHALMIC HOSPITAL,

JUDD ST., ST. PANCRAS, W.C.1.

143, Cannon Street, London, E.C.4

LIVERPOOL SCHOOL OF TROPICAL MEDICINE.

(UNIVERS[illegible]

COURSES OF [illegible]
three months)
Medicine commence on October 1st and January 7th, and for the Diploma in Tropical Hygiene on January 12th and April 26th. (Candidates for the D.T.H. must possess the D.T.M. of this University.)

For particulars apply to the Hon. Dean, Liverpool School of Tropical Medicine, Pembroke Place, Liverpool.

UNIVERSITY OF LONDON, KING'S COLLEGE.

FACULTY OF MEDICAL SCIENCE.

COMPLETE COURSES OF STUDY ARE PROVIDED FOR THE PRELIMINARY AND INTERMEDIATE EXAMINATIONS OF:

(1) The University of London.
(2) The Conjoint Examining Board of the Royal Colleges of Physicians and Surgeons; and also for
(3) The Degree in Dental Surgery (B.D.S.).
(4) The Primary Fellowship Examination of the Royal College of Surgeons.
(5) The First Professional Examination for the Licence in Dental Surgery of the Royal College of Surgeons.

The College, without in any way lengthening the duration of the Course, offers, like Oxford and Cambridge, the advantages of a broad University Education to Medical Students before they proceed with the purely clinical subjects.

Valuable Scholarships and Prizes are awarded on the results of examinations held annually.

The hostel for men students (King's College Hall, Champion Hill, S.E.5) is close to the hospital, and contains accommodation for 80 students. The hostel for women students is at 58, Queensborough Terrace, Bayswater.

For detailed prospectus of the Medical and Dental Courses and for further information apply to the Dean, Prof. R. J. S. McDOWALL, D.Sc., M.B., Ch.B., F.R.C.P.(Edin.), or to

S. T. SHOVELTON, M.A.,
Strand, W.C.2. Secretary.

THE LONDON HOSPITAL MEDICAL COLLEGE.

(University of London.)

ADVANCED MEDICINE.

A Course of Post-Graduate Instructions in Advanced Medicine suitable for candidates preparing for the M.D., M.R.C.P. Examinations will begin on Monday, *October 14th.*

The Course will comprise the examination of selected cases in the Wards, Ward Demonstrations, and instruction in Applied Physiology, Clinical Pathology, ar . . obtained on applics . WILLIAM WRIGHT, M.B., D.Sc., F.R.C.S., London Hospital Medical College, Mile End, E.

LONDON HOSPITAL MEDICAL COLLEGE.

F.R.C.S.

A COURSE OF INSTRUCTION for the Final Fellowship Examination will begin on Monday, September 2nd.

Fees: (exclusive of Operative Surgery) 20 guineas. Operative Surgery 5 guineas.

A separate entry can be made for all Classes other than those of a strictly Clinical character. (Men students only are eligible for admission.)

THE HOSPITAL FOR SICK CHILDREN,

GREAT ORMOND STREET, BLOOMSBURY, W.C.1.

THE PRINCIPAL SCHOOL OF MEDICINE IN LONDON FOR THE STUDY OF CHILDREN'S DISEASES.
RECOGNIZED BY THE UNIVERSITIES OF LONDON, OXFORD, CAMBRIDGE, &c.

252 Beds at Great Ormond Street and 45 Beds at Tadworth, Surrey.

The practice of the Hospital is open to all qualified medical men and women.

Fees for Attendance.

One month	£2 2 0	Perpetual Student's ticket	£10 10 0
Three months' course	£5 5 0	Clinical Clerks:—£1 1 0 per month.	

This Hospital contains 252 beds, with an average admission of over 6,500 in-patients per annum; whilst in the Out-patient Department about 28,000 new patients are seen each year. The Medical School is recognized by the Universities of Oxford, Cambridge, and London, and by the Conjoint Medical Board of England, as a teaching institution where two months' clerking and dressing may be carried out by any undergraduate student who is entering for a final qualifying examination. In addition, for students who have completed four years of medical study, six months of the fifth year may be spent there in clinical work under recognition from the Conjoint Board. Post-graduate instruction, open to all qualified medical men and women, is given daily in the wards, out-patient department, operating theatre, and *post-mortem* room by members of the visiting staff. In addition, special courses are arranged throughout the year, announcements of which are made from time to time, and full details of them can be obtained from the Dean or Secretary at the Hospital. Clinical clerkships in the wards, clinical assistantships in the out-patient department, and research clinical clerkships are also available for post-graduate students. Opportunities for study are also offered in the Ophthalmic, Dermatology, Dental, Radiographic, and Pathological Departments.

CERTIFICATES ARE GRANTED FOR THREE MONTHS' ATTENDANCE OR LONGER.

PATHOLOGICAL DEPARTMENT.—Facilities are offered to post-graduates for obtaining theoretical and practical instruction in Clinical Pathology and Bacteriology, and in Medical Biochemistry in the Pathological and Biochemical Laboratories.

Courses of 8 to 10 Lecture Demonstrations are given at weekly intervals twice a year in both subjects (Clinical Pathology and Bacteriology, and Biochemistry). These Lecture Demonstrations are of one or two hours' duration.

FEES.—For Course of 8 to 10 Laboratory Demonstrations in either Branch £5 5 0
For Combined Course of (*a*) Clinical Pathology and Bacteriology and (*b*) Medical Biochemistry £8 8 0

JAMES McKAY, Secretary. ERIC I. LLOYD, F.R.C.S., Dean of the Medical School.

UNIVERSITY OF BIRMINGHAM

FACULTY OF MEDICINE

(Associated with the General, Queen's, and Special Hospitals for Clinical Teaching.)

THE SESSION OPENS ON MONDAY, SEPTEMBER 30th, 1929.

The University grants Degrees in Medicine, Surgery, and Public Health, and a Diploma in Public Health; also Degrees and a Diploma in Dental Surgery.

The courses of instruction are also adapted to meet the requirements of other Universities and Licensing Bodies.

HOSPITAL APPOINTMENTS.

A large number of Resident Hospital appointments in Birmingham and District are open to qualified students of the School.

SCHOLARSHIPS, EXHIBITIONS, AND PRIZES.

Entrance and other Scholarships and Exhibitions and various Prizes and Medals are awarded annually in the Faculty of Medicine.

SCHOOL OF DENTISTRY. (University of Birmingham and Birmingham Dental Hospital.)

The School of Dentistry, in conjunction with the General and Queen's Hospitals, affords a complete curriculum for the Dental Diploma and Dental Degrees of the University and all other Licensing Bodies. There is a Dental Scholarship of the value of £46 17s. 6d. offered annually.

PRE-MEDICAL AND PRE-DENTAL EXAMINATIONS.

The necessary Courses of Instruction in Chemistry and Physics and in Biology may be attended in the University.

RESIDENCE FOR UNDERGRADUATES AND OTHER STUDENTS.

There are Halls of Residence for Men and for Women Students. A register of approved lodgings is also kept by the Secretary of the University.

For Syllabus and further information apply to Prof. J. C. BRASH, M.A., M.D., Dean.

ST. GEORGE'S HOSPITAL MEDICAL SCHOOL

(UNIVERSITY OF LONDON).

HYDE PARK CORNER, S.W.

THE HOSPITAL and MEDICAL SCHOOL occupy the finest site in London and are readily accessible from all parts of the Metropolis.

The entire teaching in the School is devoted to the subjects of the Final Examinations; in other words, is specially adapted to the interests of men from the Universities who have passed their Examination in Anatomy and Physiology.

[illegible] authorities of King's College in [illegible] idents attend at that College for [illegible] and Intermediate subjects.

FIVE ENTRANCE SCHOLARSHIPS IN ANATOMY AND PHYSIOLOGY, AND GENERAL PATHOLOGY, of the value of £120, £94 10s., £80, £70, and £50 respectively, are awarded in July to candidates who have passed the 2nd M.B. or corresponding examination. In addition, EXHIBITIONS, each of the value of £40 and up to Six in number, will be awarded to candidates of approved merit in the Entrance Scholarship Examination.

MANY VALUABLE PRIZES ARE AWARDED EACH YEAR, including the following:—Allingham Scholarship of the value of £80, Laking Memorial Prize of the value of £65, the Brackenbury Prize in Medicine, the Brackenbury prize in Surgery, and the Webb Prize in Bacteriology, each of the value of £33.

HOUSE OFFICE may be held for four, eight, or twelve months. A Student of ordinary ability should have an excellent chance of obtaining House Office and afterwards one of the following Paid appointments for a short time. Resident Assistant Physician, £250; Resident Assistant Surgeon, £250; Medical Registrar, £200; Surgical Registrar, £200; Assistant Curator of the Museum, £100; Resident Anæsthetist, £100; Resident Obstetric Assistant, £50.

The ST. GEORGE'S HOSPITAL CLUB incorporates the RUGBY FOOTBALL, CRICKET, LAWN TENNIS, BOXING, RIFLE and other Clubs, and possesses an ATHLETIC GROUND within easy reach of the Hospital, and Smoking and Luncheon Rooms on the School Premises.

Entrance Fee, £10 10s. 0d. Annual Composition Fee, which covers all courses, lectures, etc., in the Hospital and School, £42. Annual Club Subscription, £3 3s. 0d.

The Winter Session will begin on October 1st, but *students can enter at any time.*

Further information may be obtained from the Dean of the Medical School.

A. FEILING, M.D., F.R.C.P.,
Dean.

KING'S COLLEGE HOSPITAL MEDICAL SCHOOL

(UNIVERSITY OF LONDON).

Dean: H. WILLOUGHBY LYLE, M.D., B.S.Lond., F.R.C.S., J.P.

The present HOSPITAL was opened in 1913 and is one of the best equipped Hospitals in England. The importance of specialization has long been recognized by the Hospital, and it has now sixteen Special Departments, each in charge of a specialist and his staff. It is planned for 600 beds, but at present, owing to lack of funds, 200 are not yet available. It serves a population of nearly 2,000,000, and the attendances in the Casualty and Out-patient Departments during the year 1928 amounted to 285,348.

The MEDICAL SCHOOL Buildings, like those of the Hospital, are up to date and exceptionally fine. The Laboratory and Pathological Department and the Post-mortem Room are especially noteworthy.

In the Education at the Hospital a special feature has always been the individual attention given to each Student, and each subject is taught by its own specialist. There is ample opportunity for any Student who wishes to specialize in a subject to continue his studies with the help of Junior Staff appointments. With a view to ensuring better co-ordination of studies, the teaching of each of the subjects of Medicine, Surgery, and Gynæcology has been placed in charge of a member of the Senior Honorary Staff, assisted by Medical, Surgical, and Obstetric Tutors. Attached to the Gynæcological Department is a Maternity Ward, through which Students can qualify for the requirements in that subject of all the Examining Bodies.

FOURTEEN ENTRANCE SCHOLARSHIPS, of a total value of £1,530, are awarded annually.

"The PLATANES," close to the Hospital, with large grounds and tennis courts, is a residence for 80 Students.

The ATHLETIC GROUND (over six acres in extent) is within ten minutes' walk of the Hospital.

The Fee for the advanced studies is 93 guineas. The Entrance Fee of 10 guineas includes membership of the Clubs and Societies Union.

DENTAL SCHOOL. When the Hospital was built accommodation was provided for a Dental Department. This section, together with additional rooms for Dental Metallurgy, etc., is in full use by the Dental School, which was opened in October, 1923, under the direction of Mr. A. LIVINGSTON, M.B., Ch.B., Mast. Dent. Surg. A full course is given in co-operation with King's College, in preparation for Dental Degrees and Diplomas.

For Particulars, Calendar of the School, and Appointments to see the School and Hospital, application should be made to the Secretary, S. C. Ranner, M.A.Cantab., King's College Hospital Medical School, Denmark Hill, London, S.E.5.

Charing Cross Hospital Medical School

(UNIVERSITY OF LONDON)

With which is affiliated **The Royal Westminster Ophthalmic Hospital.**

OPEN TO MEN STUDENTS.

SESSIONS COMMENCE OCTOBER AND APRIL.

The most central of all the Colleges of the University. Complete Hospital and School arrangements for all departments of Clinical work.

The Institute of Pathology includes a series of Laboratories fully equipped for Student, Post-Graduate, and Research work.

Students' Club Rooms and Restaurant on the School premises.

Two Scholarships, value £120, are awarded annually for final studies for students of Oxford and Cambridge. Scholarships are also awarded in Anatomy and Physiology to students studying for the London M.B. In addition there are several Exhibitions awarded annually, particulars of which may be obtained from the Dean. Examinations for these Scholarships are held in August and March each year.

Fees 38 guineas per annum.

For Prospectus and full information apply personally or by letter to the Dean:

F. H. YOUNG, M.D., M.R.C.P., Charing Cross Hospital Medical School, London, W.C.2.

Telephone No.: REGENT 3903 and 3904.

LONDON SCHOOL OF HYGIENE AND TROPICAL MEDICINE.

(University of London)

TROPICAL MEDICINE AND HYGIENE.

The School provides two courses yearly, each of 20 weeks. The next courses commence on September 30th, 1929, and February 3rd, 1930.

DIPLOMA IN PUBLIC HEALTH.

The course of study in Public Health, covering a period of 12 calendar months, commencing on September 30th, 1929, and is so designed that students wishing to do so can proceed to the new academic diploma instituted by the University of London.

The inclusive fee of 50 guineas will cover the cost, not only of the ordinary lectures and demonstrations, but also of the necessary practical work in public health departments and instruction in infectious diseases, etc.

DIPLOMA IN BACTERIOLOGY.

The course of study, covering one academic year, commences in October.

Special advanced courses of study in various branches of Medicine and Science are given by the Professors and other teachers on the staff of the School.

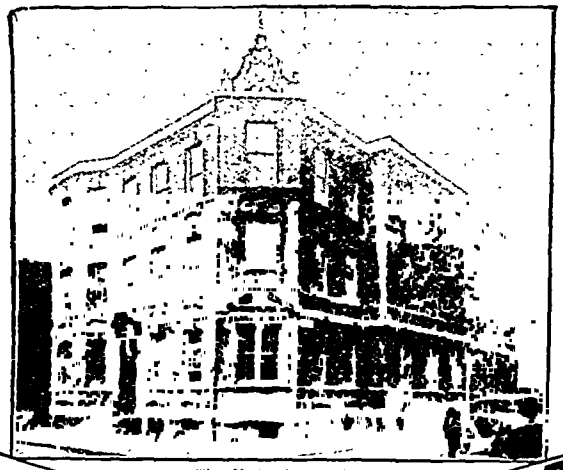
Applications for information as to the above courses and other special advanced courses of study, should be addressed to the Secretary, Keppel Street (Gower Street), London, W.C.1.

Westminster Hospital Medical School

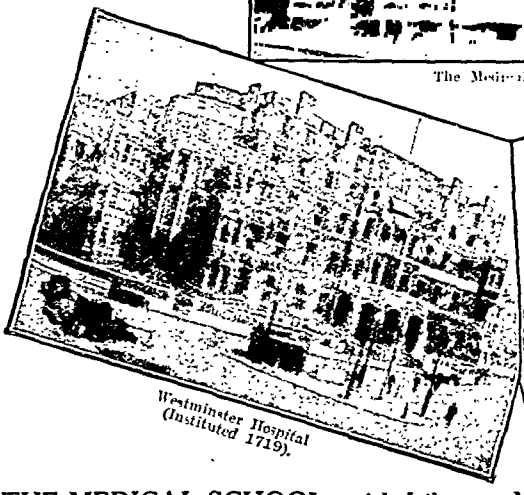
(University of London)

WINTER SESSION COMMENCES OCTOBER 1.

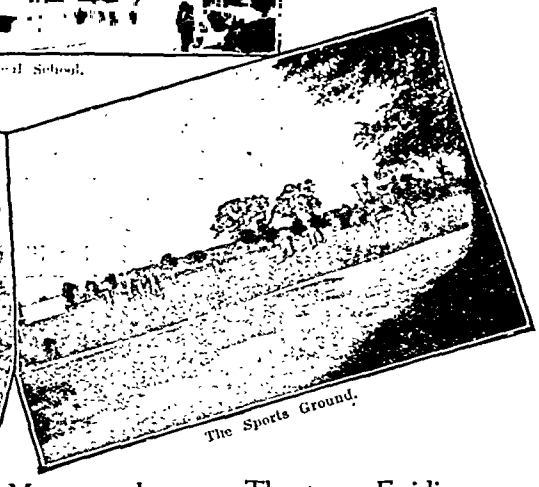
CENTRALLY SITUATED (OPPOSITE WESTMINSTER ABBEY)



The Medical School.



Westminster Hospital (Instituted 1719).



The Sports Ground.

THE MEDICAL SCHOOL, with Library, Museum, Lecture Theatres, Epidiascope, &c., is only a few minutes' walk from the Hospital. The entire teaching of the Hospital and School is devoted to the subjects of the Final Examinations. Arrangements are made for the tuition required for preliminary and intermediate subjects.

ENTRANCE SCHOLARSHIPS to the value of £350 and PRIZES to the value of £170 are awarded annually.

Fees: Annual Composition fee, £40.

Paid appointments as Medical, Surgical, and Obstetric Registrars, Casualty Officers, House Physicians, House Surgeons, and Anæsthetists, are available for Students when they have passed their examinations.

MEDICAL GRADUATES, whether qualified in this country or abroad, can obtain appointments as Clinical Assistants for duty in the Wards, Out-patients' Departments, or Special Departments.

QUALIFIED PRACTITIONERS may be appointed as Assistants in the recently opened Carlill laboratories for the purpose of engaging in research work.

Post-Graduate Classes are held annually.

The Dean or Sub-Dean will be pleased to arrange for intending students and parents to inspect the Hospital and Medical School at any time.

ONLY MALE STUDENTS ARE ADMITTED.

A prospectus and full particulars may be obtained on application to the Dean:

Dr. A. S. WOODWARK, C.M.G., C.B.E., M.D., F.R.C.P.,

Westminster Hospital Medical School, Caxton St., Westminster, S.W.1. Tel.: Victoria 0765.

Tuesdays at 5 p.m. at University College. January to March.

Anæsthetics.—H. J. SHIRLEY, C.M.G., M.D., F.R.C.S.
Alternate Tuesdays at 5 p.m. January to March.

Radiology.—D. A. IMRIE, M.D.Laus., L.R.C.P.E., L.R.C.S.E., D.M.R.E., L.D.S.
Thursdays at 5 p.m. July.

The WINTER SESSION Commences TUESDAY, OCTOBER 1st, 1929.

This Hospital and School, situated in the centre of a large population, and within a few minutes of University College Hospital, has recently been reorganized and equipped on the highest standard of modern requirements, and is admirably adapted for the teaching of students in every branch of the Science and Art of Dental Surgery. The mechanical laboratory, conservation room, and X-rays department are replete with all the latest approved appliances.

Students (men and women) enter as students of University College Hospital, and attend classes in anatomy and physiology at University College, adjacent to University College Hospital.

Each student serves as a dresser in the extraction, anæsthetic, conservation, and X-rays departments, which provides him with the opportunity of observing and actually carrying out the methods of work in all branches.

Four house surgeons are appointed half yearly.

The Calendar, containing full information as to lectures, fees, prizes, etc., may be had on application to the Sub-Dean of Dental Students, who attends the University College Hospital Medical School, University Street, Gower Street, W.C.1, on Wednesdays, at 9.30 a.m.

LONDON HOSPITAL MEDICAL COLLEGE & DENTAL SCHOOL.

THE WINTER SESSION will Open on Tuesday, October 1st.

The Hospital is the largest in England. There are 839 beds in constant use. Last year: number of in-patients 14,698; new out-patients, 96,928; attendances, 555,762; new dental patients, 5,857; major operations, 7,649.

The MEDICAL COLLEGE and DENTAL SCHOOL are essentially modern, with large laboratories equipped with the latest and the most approved appliances. The STAFF is so large as to permit of individual attention being paid to all Students.

MEDICAL UNIT.—A Clinical Unit in Medicine, under the charge of a whole-time Director, provides for the more elaborate methods of diagnosis and treatment, and takes a leading part in the initiation and co-ordination of medical research.

RESEARCH FUNDS to the value of over £113,000 permit of financial assistance being given to Students and Graduates engaged in Medical Research.

SCHOLARSHIPS and PRIZES to the value of £1,158 are awarded annually, including four Open Entrance Scholarships to the value of £350, and two Entrance Scholarships open to students of the Universities of Oxford and Cambridge to the value of £200.

APPOINTMENTS.—Over 160 Appointments are made annually from Students of the College recently qualified.

SPECIAL COURSES are held for all the University Examinations, for the Primary and Final Fellowship Examinations of the Royal College of Surgeons, and for the Membership Examination of the Royal College of Physicians.

HOSPITAL PRACTICE.—Exceptional opportunities are offered to qualified Practitioners wishing to attend the General Practice or the Practice of a Special Department of the Hospital.

A Clubs' Union, an Athletic Ground of over 13 acres, and a *Students' Hostel*, promote the recreation, health, and comfort of the Students.

For Prospectus and Particulars apply to the Dean (Professor WILLIAM WRIGHT, M.B., D.Sc., F.R.C.S.), who will be pleased to make arrangements for anyone wishing to see the Medical College and Dental School.

MILE END, E.

GUY'S HOSPITAL MEDICAL & DENTAL SCHOOLS.

(UNIVERSITY OF LONDON.)

THE HOSPITAL, which contains 646 Beds, is situated one minute's walk from London Bridge Railway Stations.

UNIVERSITY STREET, GOWER STREET, W.C.1.

MEDICAL AND SURGICAL STAFF.

Consulting Physicians—Sir THOMAS BARLOW, Bart., K.C.V.O., M.D., D.Sc., D.C.L., F.R.S., F.R.C.P., Sir JOHN ROSE BRADFORD, K.C.M.G., C.B., C.B.E., M.D., D.Sc., D.C.L., F.R.C.P., F.R.S., Dr. H. R. SPENCER, F.R.C.P., Sir GEORGE BLACKER, C.B.E., M.D., F.R.C.P., F.R.C.S.

Physicians—Dr. H. BATTY SHAW, F.R.C.P., Dr. F. J. POYNTON, F.R.C.P., Dr. C. BOLTON, C.B.E., D.Sc., F.R.C.P., F.R.S., Prof. T. R. ELLIOTT, C.B.E., D.S.O., M.D., F.R.C.P., F.R.S., Sir T. LEWIS, C.B.E., D.Sc., M.D., F.R.C.P., F.R.S., Dr. J. W. McNEE, D.S.O., F.R.C.P.

Physician to the Neurological Department—Dr. F. M. R. WALSHE, O.B.E., D.Sc., F.R.C.P.

Physician to Skin Department—Dr. A. M. H. GRAY, C.B.E., F.R.C.P., F.R.C.S.

Physicians for Mental Diseases—Dr. B. HART, F.R.C.P., Dr. A. F. TREDGOLD, F.R.C.P.

Physician for Children's Diseases—Dr. F. J. PEARSON, F.R.C.P.

Consulting Surgeons—Mr. BILTON POLLARD, B.S., F.R.C.S., Mr. RAYMOND JOHNSON, O.B.E., B.S., F.R.C.S., Mr. PERCY FLEMMING, B.S., F.R.C.S., Mr. H. MORRISTON DAVIES, M.S., F.R.C.S., Mr. S. SPOKES, M.R.C.S., L.D.S. (Dental), Mr. RICHARD LAKE, F.R.C.S., Mr. A. E. RELPH, M.R.C.S., L.R.C.P. (Dental).

Surgeons—Mr. WILFRED TROTTER, M.S., F.R.C.S., Mr. GWYNNE WILLIAMS, M.S., F.R.C.S., Prof. C. C. CHOYCE, C.M.G., C.B.E., B.Sc., F.R.C.S., Mr. E. K. MARTIN, M.S., F.R.C.S., Mr. JULIAN TAYLOR, M.S., F.R.C.S.

Ophthalmic Surgeons—Sir J. H. PARSONS, C.B.E., D.Sc., B.S., F.R.C.S., F.R.S., Mr. HUMPHREY NEAME, F.R.C.S.

Obstetric Surgeons—Mr. CLIFFORD WHITE, F.R.C.P., F.R.C.S., Prof. F. J. BROWNE, F.R.C.S.Ed.

Diseases of the Ear and Throat—Mr. HERBERT TILLEY, B.S., F.R.C.S., Mr. G. SECCOMBE HETT, B.S., F.R.C.S., Mr. E. A. PETERS, F.R.C.S., Mr. H. A. KISCH, B.S., F.R.C.S., Mr. J. F. O'MALLEY, F.R.C.S.

Dental Surgeons—Mr. H. J. RELPH, M.R.C.S., L.R.C.P., L.D.S., Mr. A. B. G. UNDERWOOD, M.B., B.S., L.D.S.

Radiologist—Dr. R. W. A. SALMOND, O.B.E., Ch.M.

Consulting Anæsthetists—Dr. DUDLEY W. BUXTON, M.R.C.P., Dr. A. B. KINGSFORD.

Anæsthetists—Dr. H. J. SHIRLEY, C.M.G., F.R.C.S., Dr. F. S. ROOD, Dr. C. W. MORRIS, Dr. S. HUTCHINSON, Dr. H. N. WEBBER.

Pathology—Prof. A. E. BOYCOTT, M.A., D.M., LL.D., F.R.C.P., F.R.S.

Bacteriology—Dr. F. H. TEALE, B.Sc., F.R.C.P., Dr. H. D. WRIGHT, B.A., Ch.B., F.R.C.P.E., Dr. D. EMBLETON.

Clinical Pathology—Dr. G. W. GOODHART, M.A., B.Ch.

Morbid Anatomy—Mr. W. G. BARNARD, M.R.C.S., L.R.C.P.

Chemical Pathology—C. R. HARINGTON, M.A., Ph.D.

THE WINTER SESSION will commence on OCTOBER 1st, 1929.

THE SCHOOL IS FOR FINAL STUDIES only.

STUDENTS are prepared for the degrees of the Universities of:
OXFORD, CAMBRIDGE, LONDON, and DURHAM, and for the Diplomas of other qualifying bodies.

CLINICAL UNITS in MEDICINE, SURGERY, and OBSTETRIC MEDICINE are now in operation.—The whole-time Directors of the Units are concerned with the organization of the teaching generally, but the honorary staff are responsible for the largest share of the teaching in the wards and Out-patient Department of the Hospital. The new Obstetric Hospital is now finished and in full occupation.

Director of the Medical Unit—Prof. T. R. ELLIOTT. Assistants—Mr. W. H. CRAIB, Dr. C. J. FULLER, Mr. H. A. HARRIS, Mr. A. M. RICHARDS, Mr. E. A. BLAKE-PRITCHARD, Mr. J. D. PROCTOR.

Director of the Surgical Unit—Prof. C. C. CHOYCE. Assistants — Mr. A. J. GARDHAM, Mr. F. J. F. BARRINGTON, Mr. R. S. PILCHER.

Director of the Obstetric Unit—Prof. F. J. BROWNE. Assistants—Dr. L. H. W. WILLIAMS, Mr. N. L. WHITE, Miss G. H. DODDS.

DENTAL STUDENTS can obtain a complete curriculum at University College, and at University College Hospital Dental School (The National Dental Hospital, Great Portland Street). This Hospital has recently been reorganized and equipped on the highest standard of modern requirements, and is admirably adapted for the teaching of Students in every branch of the science and art of Dental Surgery.

FEES.—For the Final Course: 112 guineas if paid in one sum, or 115 guineas paid in two instalments of 70 and 45 guineas.

APPOINTMENTS.—Forty-seven appointments are open during the year to students, and paid appointments to the annual value of over £2,000.

SCHOLARSHIPS, EXHIBITIONS, and PRIZES, of the value of over £1,000, are awarded annually. Amongst the most important are:

GRAHAM SCHOLARSHIP in Pathology, £300 per annum.

LESLIE PEARCE GOULD SCHOLARSHIP, awarded every two years, about £200.

RADCLIFFE CROCKER TRAVELLING SCHOLARSHIP in Dermatology, awarded every five years, about [£280.

MAGRATH SCHOLARSHIP in Clinical Medicine, about £150.

PERCIVAL ALLEYN PRIZE, about £75.

ATCHISON SCHOLARSHIP, about £55 per annum; tenable for two years.

ATKINSON MORLEY SCHOLARSHIP, £45 per annum; tenable for three years.

BUCKNILL SCHOLARSHIP entitles the holder to the Intermediate Medical Course at University College, and for the Final Course at the Medical School.

GOLDSMID EXHIBITIONS. Two Exhibitions, the subjects of the Examination being any two of the following subjects: Anatomy, Physiology, General Pathology, awarded annually towards the end of the Summer Session, and entitle to course for Final Medical Examination.

All further information and Prospectus can be obtained from the Secretary, and the Dean can be interviewed at any time by appointment.

Dean—A. M. H. GRAY, C.B.E., M.D., F.R.C.P., F.R.C.S.

Vice-Dean—GWYNNE WILLIAMS, M.S., F.R.C.S.

Sub-Dean for Dental Students—J. L. DUDLEY BUXTON, L.M.S.S.A., L.D.S. Secretary—R. SLOLEY.

NATIONAL HOSPITAL FOR DISEASES OF THE HEART

WESTMORELAND STREET, W.1.

The Clinical Practice of the Hospital in the Out-patient Department and the Wards is open to Post-Graduates. Fees: One Month £2 2s.; Three Months £5 5s.

Under-Graduates who have completed their fourth year are admitted to the Practice of the Hospital at specially reduced fees.

Special Courses of two weeks' duration are held in January, July, and October. Fee £7 7s.

Further particulars may be obtained on application to the Dean or the Secretary at the Hospital.

WEST END HOSPITAL FOR NERVOUS DISEASES.

OUT-PATIENT DEPARTMENT, WELBECK STREET, W.1.

IN-PATIENT DEPARTMENT, GLOUCESTER GATE, REGENT'S PARK, N.W.1.

Recognized by the University of London.

Courses of SPECIAL CLINICAL DEMONSTRATIONS on selected cases, as advertised, are given in March-April and November-December.

The general practice of the hospital is conducted daily (Saturdays excepted).

The Savill Prize (value £15) and medal is offered biennially for the best thesis on a neurological subject submitted by Post-Graduates who have attended the hospital practice on not less than 10 occasions.

A limited number of appointments as Hon. Clinical Assistants are open to Post-Graduates.

For particulars of the above apply to C. WORSTER-DROUGHT, M.D., M.R.C.P., Dean, or to the Secretary of the Hospital at 73, Welbeck Street, W.1.

THE

METROPOLITAN EAR, NOSE, & THROAT HOSPITAL

(1838) (INCORPORATED),

FITZROY SQUARE, LONDON, W.1.

FACILITIES FOR CLINICAL WORK are afforded to Medical Practitioners and Students. Fee for one month, 3 Guineas; for three months, 5 Guineas.

PRACTICAL DEMONSTRATIONS are given daily (Saturdays excepted), at 3 p.m., in the manipulation of instruments used in the Diagnosis and Treatment of Diseases of the Ear, Nose, and Throat.

CLINICAL ASSISTANTS are appointed as vacancies occur, and have responsible duties.

Further particulars may be obtained from the Secretary.

L. L. PHILLIPS.

BETHLEM ROYAL HOSPITAL,

Lambeth Road, S.E.1.

A COURSE of LECTURES and PRACTICAL INSTRUCTION

FOR THE

DIPLOMA IN PSYCHOLOGICAL MEDICINE

(OF THE UNIVERSITIES OF LONDON, CAMBRIDGE, DURHAM, &c., AND THE CONJOINT BOARD).

WILL BE GIVEN at the above Hospital, commencing SEPTEMBER 24th, 1929.

For Syllabus and further particulars apply to the Physician-Superintendent.

UNIVERSITY OF LONDON

OPHTHALMIC HOSPITAL MEDICAL SCHOOL.

ROYAL LONDON OPHTHALMIC HOSPITAL

(Moorfields Eye Hospital), CITY ROAD, E.C.1.

Qualified Medical Practitioners and Registered Medical Students may enter on the Practice of the Royal London Ophthalmic Hospital (Moorfields) at any time, and are, on certain conditions, eligible for appointment as Chief Clinical Assistant, Clinical Assistant and Junior Assistant.

Courses of Instruction, extending over a period of five months, begin in OCTOBER and MARCH.

1. Practical Refraction Classes.
2. Methods of examination and use of the ophthalmoscope.
3. Lectures every afternoon on the following subjects: (*a*) Anatomy, including Embryology and Normal Histology; (*b*) Physiology; (*c*) Optics, including Physiological Optics; (*d*) Pathology and Bacteriology; (*e*) Ophthalmic Medicine and Surgery, consisting of: Medical Ophthalmology, External Diseases of the Eye, Motor Anomalies and Squint, Diseases of the Retina and Optic Nerve, Diseases of the Uveal Tract.
4. Ophthalmoscopic Conditions: a practical class with demonstrations each week at 5 p.m.
5. Clinical Lectures.
6. Occasional Lectures on subjects allied to Ophthalmology.
7. Operative Surgery. In these classes the usual operations are performed by the student upon pigs' eyes.
8. Practical Pathology. A course of demonstrations on the normal and morbid histology of the eye is given by the pathologist in the laboratory.
9. Practical Bacteriology.
10. Classes in Radiography.
11. Physico-therapy (Ultra-violet Light, Diathermy, etc.).
12. Slit-lamp Microscopy.

FEES.—A composition fee of 31 guineas will admit Students once to all the lectures and classes (except the classes on Physico-Therapy, and Slit-lamp Microscopy, and the examination fee).

DIPLOMA IN OPHTHALMIC MEDICINE & SURGERY & OTHER DEGREES IN OPHTHALMOLOGY.

The above complete curriculum is specially designed to meet the requirements of candidates entering for these examinations.

Fees for the Practice of the Hospital:

Perpetual	£5 5 0	Two months	£2 2 0
Three to six months	£3 3 0	One month	£1 1 0

Clinical work begins at 9 a.m. daily. Operations are performed between 10 a.m. and 1 p.m.

For further particulars apply to the SECRETARY to the Medical School at the Royal London Ophthalmic Hospital, City Road, E.C.1; or to the Dean, CHARLES GOULDEN, O.B.E., M.D., M.Ch., F.R.C.S.

ST. THOMAS'S HOSPITAL MEDICAL SCHOOL

(UNIVERSITY OF LONDON).

THE WINTER SESSION BEGINS on MONDAY, OCTOBER 7th, 1929.

SITE.—The Hospital occupies the finest open site in London, facing the River and the Houses of Parliament.

SCIENCE, ANATOMY, AND PHYSIOLOGY.—Classes and Lectures in all Elementary and Intermediate subjects provide complete instruction for the University and the Conjoint Board Examinations.

CLINICAL WORK.—The facilities for Clinical work are second to none in London. Clerks and Dressers, who work under the immediate supervision of the Staff, are appointed every three months in all General and Special Departments of the Hospital.

SPECIAL DEPARTMENTS.—The Special Departments in the Hospital provide Clinical Instruction in all Special subjects.

In connection with the DEPARTMENT OF OBSTETRICS AND GYNÆCOLOGY all Students attend the practice of the MATERNITY WARD before proceeding to work in the district.

THE PRIMARY F.R.C.S. CLASSES will commence on Monday, September 9th.

THE FINAL F.R.C.S. COURSE will commence September 30th (provisional).

ENTRANCE SCHOLARSHIPS.—Two in Arts, free course for first year of Study. Two in Science (Pre. Sci. Standard) £150 and £60. One for University Students (Anatomy, Physiology, Pathology, Applied Chemistry, any two subjects) £100.

ST. THOMAS'S HOUSE.—A residential Club for Students has recently been opened, providing accommodation for some 60 resident Students, and including spacious Club rooms, etc. The SPORTS GROUND is within easy reach of the Hospital.

ANNUAL FEE.—£50 for each Year of Study. The Annual Fee covers the cost of all Lectures, Classes, etc., except the following: Vaccination, £1 11s. 6d.; Pharmacy, £3 3s. 0d.; "Fevers," £3 3s. 0d.

AMALGAMATED CLUBS: Entrance Fee £2 2s. 0d.; Annual Subscription £5 5s. 0d.

Full particulars may be had by application to:

R. J. C. THOMPSON, C.M.G., D.S.O., M.D.Durh., M.R.C.P.Lond.,
Medical Secretary to the School, St. Thomas's Hospital, Lambeth Palace Road, S.E.1.

Professor L. S. DUDGEON, C.M.G., C.B.E., F.R.C.P.Lond., Dean.

THE LONDON SCHOOL OF DERMATOLOGY

St. John's Hospital for Diseases of the Skin, Leicester Square, W.C.2

THE CHESTERFIELD LECTURES, constituting a systematic Course in Dermatology, will be given at 5 p.m. on Tuesdays and Thursdays from October to March.

SYLLABUS—WINTER SESSION—1929-30.

1929.		Subject.	Lecturer.
Oct. 3	Thurs.	Introductory	Dr. J. H. Stowers.
,, 8	Tues.	Anatomy and Physiology of the Skin	Dr. W. N. Goldsmith.
,, 10	Thurs.	Morphology and Histopathology of Elementary Lesions	Dr. J. M. H. MacLeod.
,, 15	Tues.	Bacteriology and Mycology...	Dr. H. W. Barber.
,, 17	Thurs.	Pathology Demonstration ...	Dr. H. G. Burford.
,, 22	Tues.	Immunity and Anaphylaxis	Dr. H. W. Barber.
,, 24	Thurs.	Principles of Treatment ...	Dr. W. Griffith.
,, 29	Tues.	Principles of Treatment. Local.	Dr. K. Sibley.
Nov. 5	Tues.	Diseases due to Animal Parasites	Dr. H. MacCormac.
,, 7	Thurs.	Occupational Dermatitis ...	Dr. W. J. O'Donovan.
,, 12	Tues.	Nævi	Dr. Wilfrid Fox.
,, 14	Thurs.	Pathology Demonstration ...	Dr. H. G. Burford.
,, 19	Tues.	Leprosy	Dr. J. A. Drake.
,, 21	Thurs.	Tuberculosis Cutis (1) ...	Dr. A. Whitfield.
,, 26	Tues.	Tuberculosis Cutis (2) ...	Dr. A. Whitfield.
,, 28	Thurs.	Acne. Rosacea	Dr. H. Haldin-Davis.
Dec. 3	Tues.	Cutaneous Syphilis (1) ...	Dr. A. C. Roxburgh.
,, 5	Thurs	Cutaneous Syphilis (2) ...	Dr. A. C. Roxburgh.
,, 10	Tues.	Erythemato-squamous Eruptions	Dr. S. E. Dore.
,, 12	Thurs.	Pigmentation of the Skin ...	Dr. W. N. Goldsmith.

1930.		Subject.	Lecturer.
Jan. 9	Thurs.	Lichen Planus	Dr. W. N. Goldsmith.
,, 14	Tues.	Eruptions due to Physical Agents	Dr. A. C. Roxburgh.
,, 16	Thurs.	Ringworm Infections ...	Dr. J. M. H. MacLeod.
,, 21	Tues.	Erythema Multiforme ...	Dr. J. E. M. Wigley.
,, 23	Thurs.	Pathology Demonstration ...	Dr. H. G. Burford.
,, 28	Tues.	Exfoliative Dermatitis ...	Dr. W. J. O'Donovan.
,, 30	Thurs.	Pruritis. Prurigo. Lichenification	Dr. H. Haldin-Davis.
Feb. 4	Tues.	Affections of the Hair and Hair Follicles	Dr. S. E. Dore.
,, 6	Thurs.	Xanthoma. Herpes	Dr. A. M. H. Gray.
,, 11	Tues.	Ulcus Molle	Dr. E. Graham Little.
,, 13	Thurs.	Lupus Erythematosus ...	Dr. J. E. M. Wigley.
,, 18	Tues.	Staphylococcal Infections ...	Dr. G. B. Dowling.
,, 20	Thurs.	Pathology Demonstration ...	Dr. I. Muende.
,, 25	Tues.	Seborrhœa. Seborrhœic Dermatitis	Dr. G. B. Dowling.
,, 27	Thurs.	Electrotherapeutics	Dr. K. Sibley.
Mar. 4	Tues.	Eczema (1)	Dr. W. Griffith.
,, 6	Thurs.	Eczema (2)	Dr. W. Griffith.
,, 11	Tues.	Leukæmia Cutis. Mycosis Fungoides	Dr. J. E. M. Wigley.
,, 13	Thurs.	Pemphigus & Allied Eruptions	Dr. J. E. M. Wigley.
,, 18	Tues.	Mycotic Diseases	Dr. G. B. Dowling.
,, 20	Thurs.	Pathology Demonstration ...	Dr. I. Muende.

the required standard is reached.

CLINICS.—Instruction will be given daily in the Out-Patient Department, as follows:

Monday, 2 p.m. ...	Dr. Griffith.	Wednesday, 2 p.m. ...	Dr. Dowling.	Friday, 2 p.m. ...	Dr. Roxburgh
6 p.m. ...	Dr. Dore.	6 p.m. ...	Dr. Wigley.	6 p.m. ...	Dr. Dowling.
Tuesday, 2 p.m. ...	Dr. Goldsmith.	Thursday, 2 p.m. ...	Dr. Sibley.	Saturday, 2 p.m. ...	The Medical Registrar.
6 p.m. ...	Dr. Wigley.	6 p.m. ...	Dr. Goldsmith.		

LABORATORY.—Arrangements can be made for Classes, individual instruction or for research work. For particulars and fees apply to the Dean.

FEES.—For Hospital Practice, including Lectures, One Guinea per month; six months, Five Guineas. *Registered Medical Students may attend the Lectures free on signing their names and giving the name of their Hospital.*

Medical Practitioners will be welcomed as occasional visitors on presentation of their cards.

For further particulars apply to the Dean.

J. E. M. WIGLEY, M.B., Dean.

ST. BARTHOLOMEW'S HOSPITAL AND COLLEGE

(UNIVERSITY OF LONDON)

WINTER SESSION BEGINS OCTOBER 1ST, 1929.

THE HOSPITAL has 757 Beds and the MEDICAL COLLEGE contains large Lecture Rooms and Laboratories, as well as a Museum and a Library.

Every Special Branch of Medicine and Surgery has a Department.

ENTRANCE SCHOLARSHIPS.

Four Entrance Scholarships are awarded in September, of the aggregate value of £325. Other Scholarships and Prizes amount to about £875 annually.

PRELIMINARY SCIENCES.

Biology, Chemistry, and Physics are fully taught in the Laboratories apportioned to these subjects.

HOSPITAL APPOINTMENTS.

Forty House Physicians and House Surgeons are appointed annually from those Students who have passed their final qualifying examination.

Five hundred and sixty Ward Clerkships and Dresserships are open annually to Students before qualification.

STUDENTS' UNION.

The Union possesses a Club Ground of ten acres within easy reach of the Hospital.

HIGHER EXAMINATIONS.

Special Classes are held for M.D., F.R.C.S., etc.

For further particulars apply, personally or by letter, to—

THE DEAN OF THE MEDICAL COLLEGE, St. Bartholomew's Hospital, London, E.C.1.

THE UNIVERSITY OF LIVERPOOL.

FACULTY OF MEDICINE.

THE MEDICAL SCHOOL provides complete courses of instruction for the Examinations of the University of Liverpool, and also meets the requirements of other Universities and Examining Bodies in the United Kingdom.

Other Schools of the Faculty are:—The School of Dental Surgery, the School of Hygiene, the School of Tropical Medicine, and the School of Veterinary Science.

DEGREES AND DIPLOMAS IN THE FACULTY OF MEDICINE.

Bachelor of Medicine & Bachelor of Surgery	M.B., Ch.B.	Master of Veterinary Science	M.V.Sc.
Doctor of Medicine	M.D.	Doctor of Veterinary Science	D.V.Sc.
Master of Surgery	Ch.M.	Doctorate in Philosophy	Ph.D.
Master of Hygiene	M.H.	Licence in Dental Surgery	L.D.S.
Master of Orthopædic Surgery	M.Ch.Orth.	Diploma in Public Health	D.P.H.
Bachelor of Dental Surgery	B.D.S.	Diploma in Tropical Medicine	D.T.M.
Master of Dental Surgery	M.D.S.	Diploma in Tropical Hygiene	D.T.H.
Bachelor of Veterinary Science	B.V.Sc.	Diploma in Veterinary Hygiene	D.V.H.
		Diploma in Medical Radiology & Electrology	D.M.R.E.

Valuable Fellowships, Scholarships, and Prizes are offered for competition each year.

THE CLINICAL SCHOOL consists of FOUR GENERAL HOSPITALS: The Royal Infirmary, the Royal Southern Hospital, the David Lewis Northern Hospital, and the Stanley Hospital; and of FIVE SPECIAL HOSPITALS: The Eye and Ear Infirmary, the Hospital for Women (including the Samaritan Hospital), the Royal Liverpool Children's Hospital, the Liverpool Maternity Hospital, and the St. Paul's Eye Hospital.

These Hospitals contain in all about 1,500 Beds.

The organization of these Hospitals to form one teaching Institution provides the Medical Student and Medical Practitioner with a field for clinical education and study which is unrivalled in extent in the United Kingdom.

Infectious Diseases are studied in the Local and District Hospitals, and Mental Diseases at the County Mental Hospital, Rainhill.

For information on all matters concerning the curriculum application should be made to the Dean of the Faculty of Medicine, the University of Liverpool.

W. J. DILLING, Dean.

UNIVERSITY OF MANCHESTER.

FACULTY OF MEDICINE.

The WINTER SESSION commences on OCTOBER 3rd.

The Laboratories and Museums afford every facility to Students and Graduates for Practical Instruction, as well as for Original Research.

SCOPE OF INSTRUCTION.

Complete Courses of Instruction are offered for the Examinations of the University of Manchester, and also for the Examinations of other Examining Bodies in the United Kingdom. Post-Graduate Courses are held in preparation for the Diploma in Psychological Medicine (Manch.), the Certificate in Venereal Diseases, and in various branches of Medicine and Surgery. In the Dental Department Complete Courses are given preparing for the Degrees and Diploma in Dentistry granted by the University, as well as for the Diploma of the Royal College of Surgeons of England, and other Dental Diplomas. The Public Health Laboratories are situated at a short distance from the University; the fullest opportunities are offered to Graduates and others in preparation for the Diplomas in Bacteriology, in Public Health, and in Veterinary State Medicine, and for Special Certificates in School Hygiene and Factory Hygiene. Particulars may be obtained from the Dean of the Medical School.

OPPORTUNITIES FOR CLINICAL STUDY.—ROYAL INFIRMARY AND OTHER HOSPITALS.

The Clinical Instruction is given in the new Royal Infirmary, opened in 1909 on a site near to the Medical School. It is provided with every modern requirement for the treatment of the sick and the investigation of disease. Instruction in Special Subjects is given in other Hospitals associated with the University. A large number of beds in the General and in the Special Hospitals are available, thus affording unrivalled opportunities for Clinical Study.

1. The Manchester Royal Infirmary	614 beds	6. Fever Hospital for Infectious Diseases	600 beds
2. The St. Mary's Hospitals for Women and Children	216 beds	7. Special Hospitals for Diseases of the Ear, Throat and Chest, Skin, and the Christie Cancer Hospital	252 beds
3. Manchester Children's Hospital	190 beds	8. Dental Hospital of Manchester	
4. Manchester Royal Eye Hospital	148 beds	9. Ancoats Hospital	136 beds
5. Manchester Northern Hospital for Women and Children	73 beds	10. Salford Royal Hospital	263 beds

HOSPITAL APPOINTMENTS.

In consequence of the large number of Hospitals associated with, or in the vicinity of, the University, exceptional opportunities are offered to Graduates to obtain Resident Hospital Appointments.

SCHOLARSHIPS, EXHIBITIONS, AND PRIZES.

Two Open Entrance Scholarships for Graduates, each of the value of 160 guineas, are offered yearly in July. In addition, the Dreschfeld Scholarship of £30 per annum, the John Russell Medical Entrance Scholarship of £45 per annum, and other Entrance Scholarships of the value of £30 to £40 a year for two or three years, are also tenable in the Medical Faculty.

Fellowships, Scholarships, etc., are also offered for competition to Students of the Faculty.

RESIDENCE FOR UNDERGRADUATES.

There are Halls of Residence both for Men and for Women Students. A list of registered lodgings can be obtained. Prospectuses will be forwarded on application to the Registrar.

MANCHESTER UNIVERSITY MEDICAL SCHOOL.

POST-GRADUATE COURSES in MEDICINE and SURGERY.

The following arrangements have been made for Post-Graduate teaching in Manchester during 1929-30:

1. INTENSIVE COURSES:
   - (a) In Medicine and Surgery (Salford Royal Hospital), September 23rd to 27th inclusive. Fee £3 3s.
   - (b) In Fractures (Ancoats Hospital), October 7th to 11th inclusive. Fee £3 3s.
   - (c) In Oto-Laryngology (Ancoats Hospital), March 3rd to 8th inclusive. Fee £3 3s.
2. PART-TIME COURSES:
   - (a) In Diseases of the Eye, Tuesdays and Thursdays, October 8th to November 14th, at 5 p.m. Fee £3 3s.
   - (b) In Diseases of the Skin, Tuesdays and Fridays, February 4th to March 14th, at 5 p.m. Fee £3 3s.
   - (c) In Bacteriology and Immunity, Wednesdays and Fridays, University terms, Michaelmas and Lent, from 3 to 6 p.m. Fee £10 10s.
3. A POST-GRADUATE DAY (Ancoats Hospital). Every Thursday during University terms, 10 a.m. to 5.30 p.m., commencing October 10th. Lectures, Demonstrations, and Practical work. No fee.
4. CLINICAL ASSISTANTSHIPS: Fee £4 4s. per month.

Syllabus and other information may be had on application to the Dean of the Medical School.

UNIVERSITY OF DURHAM COLLEGE OF MEDICINE, NEWCASTLE-UPON-TYNE.

The Degrees in Medicine, Surgery, Hygiene, and Dentistry, the Diploma in Public Health, the Diploma in Psychiatry, and the Licence in Dental Surgery of the University of Durham are open to men and women.

The WINTER SESSION, 1929-30, will be commenced on WEDNESDAY, OCTOBER 2nd.

Students can complete, at the University of Durham College of Medicine, Newcastle-upon-Tyne, the entire course of professional study required for the above degrees, diplomas, and licence; also for the Examinations of the Royal Colleges of Physicians and Surgeons and other Examining Bodies.

Hospital practice is carried out at the Royal Victoria Infirmary, a general hospital containing more than 550 beds, and there are facilities for the study of the various special subjects. General and Special Post-Graduate Courses are held.

Practical Midwifery can be studied at the Princess Mary Maternity Hospital, which contains 90 beds, with an annual indoor and outdoor attendance on 3,000 cases. Lectures are given on Psychological Medicine in the College of Medicine, and clinical instruction at the Mental Hospital, Newcastle. Special Courses of Instruction in Outdoor Sanitary Practice and in the Hospital for Infectious Diseases are given by the City Medical Officer of Health.

Particulars may be obtained from the DEAN of the College.

ROYAL COLLEGE of PHYSICIANS of EDINBURGH ROYAL COLLEGE of SURGEONS of EDINBURGH ROYAL FACULTY of PHYSICIANS and SURGEONS of GLASGOW.

COPIES OF REGULATIONS for the TRIPLE QUALIFICATION (L.R.C.P.E., L.R.C.S.E., and L.R.F.P. & S.G.), and the DIPLOMA IN PUBLIC HEALTH, containing Dates of Professional Examinations for the year 1929-30, Curriculum etc., may be had on application to Mr. DAVID THOMSON, 49, George Square, Edinburgh, or to Mr. WALTER BURNS, 242, St. Vincent Street, Glasgow, Inspectors and Treasurers at Edinburgh and Glasgow respectively.

ST. MUNGO'S COLLEGE, GLASGOW.

THE MEDICAL SCHOOL OF THE GLASGOW ROYAL INFIRMARY.

SESSION 1929-30.

The WINTER SESSION will be opened on MONDAY, OCTOBER 14th, 1929.

LECTURES AND DEMONSTRATIONS.

*Elementary Physics, 4 p.m., 4 days weekly.—Prof. Cameron, B.Sc.
*Practical Chemistry, one day per week.—Prof. Alex R. Steven, B.Sc., F.I.C.
*Chemistry, 9 a.m.—Prof. Alex R. Steven, B.Sc., F.I.C.
Zoology (including practical class).
*Senior Anatomy, 11 a.m., Junior Anatomy, 3 p.m., Practical Anatomy, 9 a.m. to 5 p.m.—Prof. James Batttersby, F.R.C.S.(Eng.), F.R.F.P.S.G.
*Surgery, 11 a.m., Operative Surgery, 4 p.m.—Prof. John A. C. Macewen, M.B., C.M., B.Sc., F.R.F.P.S.G.
Physiology, 12 noon.—Prof. Faulds, M.B., C.M., F.R.F.P.S.G.
Clinical Surgery, 9 a.m.—The Surgeons of the Glasgow Royal Infirmary.
*Midwifery, 2 p.m.—Prof. R. A. Lennie, M.B., Ch.B., F.R.F.P.S.G.
*Practice of Medicine, 12 noon.—Prof. John Henderson, M.D., F.R.F.P.S.G.
*Clinical Medicine, 9 a.m.—The Physicians of the Glasgow Royal Infirmary.
Materia Medica, 1 p.m., or as arranged.—Prof. Crawford, M.D., F.R.F.P.S.G.
*Pathology, 3 p.m.—Pathologist to Royal Infirmary.
*Ophthalmology, 3 p.m., Tuesdays and Fridays, or as may be arranged.—Professor Barrie, M.B., Ch.B., F.R.F.P.S.G.
*Diseases of the Throat, Nose, and Ear, 11 a.m.—Prof. James Harper, M.A., M.B., Ch.B., F.R.F.P.S.G.
Diseases of the Skin, twice weekly as may be arranged.—Prof. George Harvey, M.B., Ch.B.
*Gynæcology, 12 noon.—Prof. R. A. Lennie, M.B., Ch.B., F.R.F.P.S.G.
Hospital and Dispensary, daily, 2 p.m.

The fees for all the Lectures, including Hospital attendance necessary for candidates for the diplomas of the English or Scotch Colleges of Physicians and Surgeons, amount to about £100.

Students who have fulfilled the conditions of the Carnegie Trust as regards Scottish birth or extraction and Preliminary Examination are eligible for the benefits of this Trust during the whole course of their studies at St. Mungo's College.

The Syllabus of the Medical Curriculum, giving particulars of the classes, fees, etc., may be had gratis on application to the Secretary of the Medical Faculty, 86, Castle Street, Glasgow, or from

THOMAS B. FERGUSON, Secretary.
97, West Regent Street, Glasgow.

*These classes qualify for graduation in Medicine in the University of Glasgow.

UNIVERSITY of EDINBURGH.

DIPLOMA IN RADIOLOGY.

COURSES OF INSTRUCTION for the Diploma in Radiology will commence in the beginning of October, 1929.

As the number of candidates is limited, early application is essential.

Particulars may be obtained from the Dean of the Faculty of Medicine.

W. A. FLEMING,
Secretary to the University.

UNIVERSITY OF OXFORD.

DIPLOMA IN OPHTHALMOLOGY.

The next EXAMINATION begins on MARCH 17th, 1930. The two months' COURSE OF INSTRUCTION starts on JANUARY 20th, 1930.

For further information apply to—

P. H. ADAMS,
6, Holywell, Oxford. Margaret Ogilvie Reader in Ophthalmology.

UNIVERSITY OF CAMBRIDGE

Diplomas in (a) PUBLIC HEALTH, (b) HYGIENE (for foreign graduates), (c) TROPICAL HYGIENE.

in the Subjects of the October 9th, 1929 obtained from Mr. J. E. Chemical Laboratory, ge.

Royal College of Physicians OF EDINBURGH.

The EXAMINATIONS for the LICENCE of the College (as a single qualification) for the ensuing year will be held on the *First Wednesday* and the following days of every month (except September and October).

Candidates for the LICENCE (as a single qualification) must send their names to the Secretary one week before the date of the Examination at which they propose to appear.

The EXAMINATIONS for the MEMBERSHIP of the College are held on the *Second Tuesday* and the following days of *January, April, July,* and *October.*

Candidates for the MEMBERSHIP must submit their applications and testimonials to the Secretary one month before the date at which they wish to appear for Examination.

For the Regulations in regard to the various qualifications granted by the College, and all other information, application may be made to the Secretary.

THE UNIVERSITY OF LEEDS

FACULTY OF MEDICINE

SCHOOL of MEDICINE and THE GENERAL INFIRMARY at LEEDS

The First Term begins on **October 1st, 1929.**

The degrees of M.B., Ch.B., Ch.M. and M.D. are conferred, and diplomas in Public Health and Psychological Medicine are granted by the University.

The systematic Classes and Lectures are held in the School of Medicine of the University while the Clinical instruction is given in the General Infirmary. The combined courses of study are arranged to meet the University Regulations in the first instance, but they also afford every opportunity for students preparing for the examinations of any licensing body.

The instruction in the subjects for the First Examination is given in the Department of Science of the University.

The Composition Fee for the Academic Courses and Clinical instruction is £237.

For further particulars application should be made:—

Regarding instruction given at the University to
The Academic Sub-Dean,
School of Medicine,
Leeds.

Regarding instruction given at the Infirmary to
The Clinical Sub-Dean,
General Infirmary,
Leeds.

THE UNIVERSITY OF LEEDS

SCHOOL OF DENTISTRY

The First Term begins on **October 1st, 1929.**

The degrees of B.Ch.D. and M.Ch.D., as well as a diploma, L.D.S., are conferred by the University.

The systematic Classes and Lectures are held in the School of Medicine and School of Dentistry of the University, while the clinical instruction is given in the Leeds General Infirmary and School of Dentistry. The combined courses of study are arranged to meet the University Regulations in the first instance, but they also afford every opportunity for study to students preparing for any of the dental examinations.

Intending students can enter as pupils in the Dental School and can obtain instruction in the preliminary scientific subjects in the Department of Science of the University.

For further particulars application should be made:—

Regarding instruction given at the University to
The Academic Sub-Dean,
School of Medicine,
Leeds.

Regarding clinical instruction
The Warden,
School of Dentistry, Leeds.

THE UNIVERSITY OF SHEFFIELD.

Vice-Chancellor: Sir HENRY HADOW, C.B.E., M.A., D.Mus., LL.D.

FACULTY OF MEDICINE.

Dean: Professor J. S. C. DOUGLAS, M.A., D.M., B.Ch., M.Sc.

The University grants Degrees in Medicine (M.B., Ch.B., M.D., Ch.M.), and in Dental Surgery (B.D.S., M.D.S.). It also grants a Diploma in Dental Surgery (L.D.S.). These are all open to men and women on equal terms.

The session 1929-1930 begins on October 2nd.

Lectures and laboratory courses are given in the University, whilst clinical instruction is provided in the general and special Hospitals in the City.

Although the teaching is primarily directed towards the requirements of the University the instruction amply covers those of other examining bodies.

A number of resident hospital appointments are open to qualified students of the school.

Halls of Residence.—There are four Halls of Residence, one for men students and three for women students.

Scholarships.—A number of Entrance Scholarships are open to students wishing to enter the Faculty of Medicine. There are also post-graduate scholarships.

A prospectus of the School containing all necessary details, and also particulars of scholarships, may be obtained free from— W. M. GIBBONS, Registrar.

UNIVERSITY OF BRISTOL.

FACULTY OF MEDICINE.

Autumn Term commences 4th October, 1929.

The University grants the degrees of Bachelor of Medicine and Surgery (M.B., Ch.B.), Master of Surgery (Ch.M.), Doctor of Philosophy (Ph.D.), Doctor of Medicine (M.D.), Bachelor of Dental Surgery (B.D.S.), and Master of Dental Surgery (M.D.S.), as well as diplomas in Public Health (D.P.H.) and Dental Surgery (L.D.S.).

The lectures and laboratory courses which are given in the University, although primarily designed for the degrees and diplomas of the University, are equally adapted to those of other Universities and Examining Boards, and students preparing for such external degrees and diplomas have equal attention paid to them.

Hospital Practice and Clinical Instruction are provided in the Hospitals and Asylum of the City, associated with the University for this purpose, and students have exceptional opportunities of studying the practice of Medicine from a large variety of cases.

Women are admitted to all classes, and attend them with men. The Halls of Residence for Men and for Women Students are situated in Clifton, near the University.

INCLUSIVE FEES—

For the M.B., Ch.B., curriculum ...	205 guineas.
For the B.D.S. curriculum, including Mechanical Laboratory	215 ,,
Do. excluding Mechanical Laboratory	155 ,,
For the L.D.S. curriculum, including Mechanical Laboratory	200 ,,
Do. excluding Mechanical Laboratory	140 ,,
For Mechanical Laboratory alone ...	60 ,,

For additional particulars apply to Professor Edward Fawcett, M.D., F.R.S., Dean.

THE MIDDLESEX HOSPITAL MEDICAL SCHOOL, W.1.

(University of London.)

The Winter Session opens on October 1st.

Students wishing to enter the Medical School should apply for admission as early as possible.

The Medical School is fully equipped for teaching the entire M.B., B.S., and Conjoint curriculum, including the PRE-MEDICAL EXAMINATION IN CHEMISTRY AND PHYSICS.

VALUE OF SCHOLARSHIPS AWARDED ANNUALLY EXCEEDS £1,000.

Research Funds of over £25,000.

Parents and Guardians desiring information and advice with regard to the Medical Curriculum should write to the Dean or to the School Secretary.

The rebuilt West Wing of the Hospital, representing the latest advances in Hospital construction, will be opened this year.

LONDON (Royal Free Hospital) SCHOOL of MEDICINE for WOMEN.

(UNIVERSITY OF LONDON.)

8, Hunter Street, Brunswick Square, W.C.1.

Full COURSES are arranged for the M.B., B.S. Degrees of the University of London, and for the Diplomas of the Royal Colleges of Physicians and Surgeons (including Pre-Medical Course).

Medical Jurisprudence.
Acting Lecturer—J. N. MEENAN, M.B., B.Ch., B.A.O., D.P.H.

Dental Surgery.
Professor—E. SHERIDAN, M.D.S., F.R.C.S.I., L.D.S.

Dental Mechanics.
Professor—J. J. POTTER, M.D.S., L.D.S.

Orthodontia.
Lecturer—LAURENCE FLANAGAN, B.D.S., M.B., B.Ch.

All Scholarship Examinations in Medicine will be held on October 1st.

Introductory Course.—Particular attention is paid to beginners, for whom a special Introductory Course is delivered at the commencement of the Winter Session, beginning on October 4th.

Regulations for Courses of Study for Degrees, and General Regulations containing information as to Scholarships, etc., may be obtained from the REGISTRAR, Medical School, Cecelia Street, Dublin.

ROTUNDA HOSPITAL, DUBLIN.

THE HOSPITAL contains 127 beds. Upwards of 2,000 maternity cases and 1,000 gynæcological patients are treated during the year. Besides the Hospital there is an extern Maternity Department with over 2,000 cases. The routine for Students consists of attendance at the Morning Lectures on Midwifery and Gynæcology, examination of patients in the Gynæcological Department, attendance at operations and all abnormal labours in the Hospital Wards and conduction of labour cases in the intern and extern departments; the Ante-Natal Clinic, the Infants' Ward and Dispensary, and Pathological Laboratory are available also. An X-Ray department is attached to the Hospital.

Qualified Students are allowed to assist at the major and perform some minor gynæcological operations.

The Hospital Courses are always going on during the year, and Students can join at any time. The Class is limited, therefore it is advisable to register in advance. Board and lodging can be obtained in the Hospital.

Extra classes in gynæcological diagnosis and operative midwifery are conducted by the Assistants to the Master.

Fees, one month, £6 6s.; months other than the first, £4 4s.; three months, £12 12s.; L.M. Course, £21.

The L.M. certificate is given to qualified practitioners on examination after six months' attendance at the Hospital.

Full particulars from Bethel Solomons, M.D., Master, Rotunda Hospital.

UNIVERSITY OF DUBLIN
SCHOOL OF PHYSIC.
TRINITY COLLEGE.

The WINTER SESSION will begin on October 1st, 1929.

All information regarding Courses for the Medical and Dental Degrees, for the Diploma in Public Health, for the Diploma in Gynæcology and Obstetrics, and for the Diploma in Psychological Medicine may be obtained on application to the Registrar, School of Physic, Trinity College, Dublin.

University College of South
WALES AND MONMOUTHSHIRE.

THE WELSH NATIONAL SCHOOL OF MEDICINE.

August 23rd, 1929.

City of Sheffield.

ASSISTANT TUBERCULOSIS OFFICER (Male).

Applications are invited for the post of Assistant Tuberculosis Officer.

Salary £600 per annum, rising to £650 by annual increments of £25. Applicants must have been graduated in Medicine and Surgery for not less than three years, and have held a Resident Hospital appointment for not less than six months.

Possession of a Diploma in Public Health, although not essential, will be considered an advantage

Applications, stating age, qualifications, and experience, together with copies of three recent testimonials, to be sent on or before September 4th to the undersigned.

Town Hall, Sheffield. F. E. WYNNE, *Medical Officer of Health.*

Ancoats Hospital, Manchester.

HOUSE SURGEON required to commence duty on October 1st, for a period of six months. Salary at the rate of £100 per annum, with board, apartments, laundry, etc. Applications, stating age, qualifications, experience (if any), with copies of three recent testimonials, to be forwarded to the undersigned on or before September 6th.

By Order of the Board,
HERBERT J. DAFFORNE,
Gen. Supt. & Secretary.

County Council of Middlesex.

ASSISTANT COUNTY MEDICAL OFFICER OF HEALTH.

The County Council of Middlesex invites applications for the appointment of an Assistant County Medical Officer of Health. Salary £750 per annum, rising by annual increments of £50 to a maximum of £1,000 per annum (no bonus), together with reasonable out-of-pocket travelling expenses.

Candidates must be registered medical practitioners, *and must also be registered in the Medical Register* as the holder of a Diploma in Sanitary Science, Public Health, or State Medicine, under Section 21 of the Medical Act, 1886.

Candidates must have held resident appointment at a Hospital and also have had practical experience in Public Health administration.

The officer appointed will have to carry out, under the supervision and control of the County Medical Officer, such duties as may be required of him. He will devote his whole time to the County service, and will not be allowed to hold any other appointments or engage in private practice.

The successful candidate will be required to contribute to the County Council's Superannuation Fund and to pass such medical examination as the County Council may direct. The appointment will be during the pleasure of the Council and subject to three months' notice on either side.

Applications, stating (1) age, (2) qualifications, and (3) experience, together with copies of not more than three recent testimonials, must be received not later than September 14th. No special application forms are provided.

Canvassing, directly or indirectly, will be a disqualification.

ERNEST S. W. HART,
Middlesex Guildhall, Westminster, S.W.1. *Clerk of the County* Council.
August 22nd, 1929.

Somerset County Council.

ASSISTANT COUNTY MEDICAL OFFICER OF HEALTH AND ASSISTANT SCHOOL MEDICAL OFFICER.

Candidates must have had previous experience of the general administration of a Public Health Department, of School Medical Inspection work and its Administration and of Mental Deficiency work. They must possess a Diploma in Public Health.

Experience in the treatment of Venereal Diseases under modern methods is also necessary.

The person appointed must devote the whole of his time to the duties of the office. He will act under the control and direction of the County Medical Officer of Health and will carry out such duties as the County Council may assign to him from time to time.

The salary will be at the rate of £720 per annum, rising by annual increments of £25 to a maximum of £840.

The appointment will be made subject to the provisions of the Local Government and Other Officers Superannuation Act, 1922. Office and travelling expenses will be provided. Particulars as to the terms of the appointment, duties, qualifications, etc., may be obtained from the undersigned.

Applications, stating age, qualifications, and *previous experience, together with copies of not* more than three recent testimonials, to be forwarded to me not later than September 14th.

Personal canvassing will be a disqualification.

County Health Dept., Boulevard, Weston-super-Mare. W. G. SAVAGE, County Medical Officer of Health.

Food Poisoning—
The Kaylene Treatment

The following letter has been received recently.

Messrs. KAYLENE, LTD.

DEAR SIRS,

I am in receipt of your sample of Kaylene, for which I thank you. I do not dispense and do not wish to be without some in the house.

My last sample was used on a patient suffering from acute Ptomaine poisoning following a meal of shell fish (mussel) at 10.30 p.m. Symptoms first appeared at 12.30 a.m., and when I saw him at 3.0 a.m. he was vomiting blood and passing almost pure blood per rectum. He had commenced cramps and nervous twitchings which would shortly have gone on to tonic convulsions. He was very collapsed and had a weak pulse. I gave him **only** Kaylene in cold water, one drachm every quarter of an hour, from 3.0 until 8.0 a.m., when I felt it safe to leave him. For the next two days Kaylene was given every one to two hours, and was then followed by Kaylene-ol. No other medication of any sort was used, and he made an excellent recovery. This follows a somewhat similar case which I treated at the end of last year.

Your excellent preparation should supplant Bismuth for any purpose.

Yours faithfully,

Physician to ———. ———, M.B.

Literature and supply for clinical trial obtainable from the manufacturers.

'CHARKAOLIN'
GRANULES

A Combination of Highly Activated Charcoal with 'Osmo' Kaolin

'Charkaolin' is a new and highly efficient agent for the treatment of intestinal infections characterized by abnormal fermentation and the formation of toxins. It combines the absorbent properties of highly activated vegetable charcoal with the well-known toxin adsorbing qualities of 'Osmo' Kaolin. It is in the form of fine, clean granules which disintegrate rapidly in water and diffuse their ingredients evenly throughout the liquid. 'Charkaolin' is tasteless, forms a fine suspension in water and is, therefore, quite easy to take.

Descriptive literature and a clinical trial sample will be sent on application.

The Therapeutic value of BRANDY—

its lifting and sustaining powers—as compared with other spirits depends on the presence or absence of the higher Alcohols or Ethers. These in turn depend on Grape, Soil, Stills employed, Climate, Storage, Selection and Experience.

It is quite easy to make a spirit from grape wine—It is neither easy nor cheap to make a Brandy containing the qualities you want.

Cognac Brandy alone provides them.

Take no risks;
ensure the results you expect

Prescribe Brandy distilled in Pot Stills from Wines grown in the best Cognac districts; Matured in warehouses which have been filled with Cognac Brandy for centuries; Made by Men with the inherited Experience of Seven Generations.

DISEASES OF THE HEART

THEIR DIAGNOSIS, PROGNOSIS, AND TREATMENT BY MODERN METHODS.

With chapters on the Ink Polygraph, Clinical Electro-Cardiography, X-Ray Examination, and Anæsthesia in relation to Cardio-Vascular Affections.

By FREDERICK W. PRICE, M.D., F.R.S.(Edin.),

Physician to the National Hospital for Diseases of the Heart; Consulting Physician to the Royal Northern Hospital, London.

Demy 8vo. Pp. 534. With 249 text figures, including 32 sphygmograms, 92 polygraphic tracings, and 87 electro-cardiograms.

NEW SECOND EDITION, 21s. net.

"By great care and by the use of an amazing amount of material, he has accomplished what many readers have been waiting for, giving us a complete account of the diagnosis, prognosis, and treatment of heart diseases by modern methods in association with all the invaluable teaching bequeathed to us by the older masters of clinical observations."—LANCET.

"The most valuable and comprehensive guide to the study of Cardiology with which we are acquainted."—NEW YORK MEDICAL JOURNAL AND RECORD.

"The book presents a comprehensive account of modern knowledge of cardiology."—BRITISH MEDICAL JOURNAL.

"In our opinion the book is indisputably the most authoritative contribution to Cardiology of our time."—FRANCO-BRITISH MEDICAL REVIEW.

"A book which we believe is destined to remain the standard work on Cardiology for many years to come."—AMERICAN MEDICINE.

"The second edition of this popular work on heart disease bears evidence of thorough revision, while the essentially clinical standpoint of the writer is maintained."—EDINBURGH MEDICAL JOURNAL.

"It may be said at once that the book adequately fulfils the purpose it has in view and is a perfectly sound, lucid, and reliable guide."—NEWCASTLE MEDICAL JOURNAL.

"Well-written, concise, and complete, containing a wealth of practical information. Obviously based upon the author's own experience and investigative work."—SURGERY, GYNECOLOGY, AND OBSTETRICS (Official Journal of the American College of Surgeons).

"Dr. Price is to be congratulated again on the reappearance in its second edition of his distinguished contribution to the increasingly important subject of Cardiology."—THE CANADIAN JOURNAL OF MEDICINE AND SURGERY.

JAEGER
Pure Wool
K K UNDERWEAR
The Medical Man's Choice
Although K K is only one of many excellent varieties of Jaeger Underwear it has special qualities which appeal to the Profession. The weight, for instance, is medium; it has been carefully chosen and does not vary—a vital consideration. Then again, the wool, which is wonderfully soft and gives real comfort, is also hard wearing.

SPHYGMOMANOMETERS

Dr. Rollier on Pigmentation

"Pigmentation of the skin is therefore not solely a defence against the irradiating rays. Nor is it merely a thermic regulator, for, if pigmented skin is more quick to act in defence against a raised temperature, it favours the rise in temperature of the deep subcutaneous layers, thus establishing a thermal flow which goes from the depths to the surface of the skin (Dorno, Sonne). This phenomenon is specially to be observed under the action of the visible rays. It is because of this that I have always insisted on the importance of the complete solar spectrum as a therapeutic entity."

The British Journal of Actinotherapy, July, 1929.

The
BRITISH HANOVIA QUARTZ LAMP CO.
SLOUGH *Ltd* BUCKS

Hanovia Introduces the

"SOLLUX 500" Lamp

Complete Solar Spectrum

The new Luminous Heat unit, for use with the stand models of the Alpine Sun and Jesionek Quartz Lamps. The ideal equipment for complete solar spectrum light therapy.

Write for Booklet 9.

"The writer now feels confident of the complete superiority of this combination of mercury-vapour and incandescent filament lamps over the open arc lamps. The dosage of the patient with ultra-violet rays can be regulated with much greater accuracy."

The Lancet, August 17th, 1929.

HYGIENIC HOMES

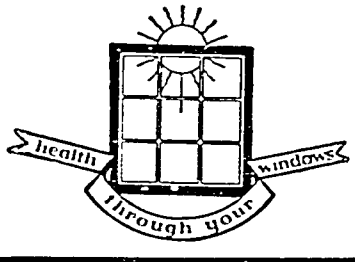
Prescribing a permanent and inexpensive Health Measure

To-day thousands of people are learning that health is shut out of their homes by windows of ordinary glass which stop the ultra-violet rays of daylight. "Vita" Glass gives those rays a permanent pathway into rooms that receive direct daylight, and acts as a health measure which can prove of material assistance to the practitioner in the treatment of his patients.

Medical men may recommend "Vita" Glass to their patients to-day with the full knowledge that its installation is inexpensive. For example, for an average-sized bay window in a modern house, the "Vita" sheet glass costs about 38/-, plus the cost of fixing.

Invented by British Science, "Vita" Glass is the only glass of its type produced by British Industry. Write for full information and prices from: THE "VITA" GLASS MARKETING BOARD, 9 Aldwych House, London, W.C.2

"Vita" Glass is obtainable from local Glass Merchants, Plumbers, Glaziers or Builders.



"Vita" is the registered Trade Mark of Pilkington Brothers, Limited, St. Helens

Post-Operative Support for your Surgical Patient.

Danger of nephroptosis following the removal of a large abdominal tumour probably indicates careful support for your patient.

Ruptured appendix with drainage places such a heavy tax upon the vitality of your patient that you may wish to recommend the wearing of an abdominal support during convalescence.

Or a sensitive scar after a gall-bladder operation may need the protection of a special support, with laparotomy pad.

This is a Supporting Corset with the front opened to show the inner belt which supports the abdomen. Adjustment of the belt is made from the outside of the support.

After any abdominal operation, a Spencer supporting corset or abdominal belt gives your patient great comfort and sense of security. The support can be made of light as well as of firm material. It can be soft and pliable for comfort. But because each Spencer support is especially designed for the person who will wear it, it will give the support that you want your patient to have.

The Spencer Corsetière will call at your surgery or at your patient's home to take the necessary measurements, and to get your special instructions about the case in hand.

We issue booklets on the use of Spencer Supports for the relief of sacro-iliac strain, hernia, enteroptosis, movable kidney, and for maternity and post-partum wear. We will gladly send them in which you are interested.

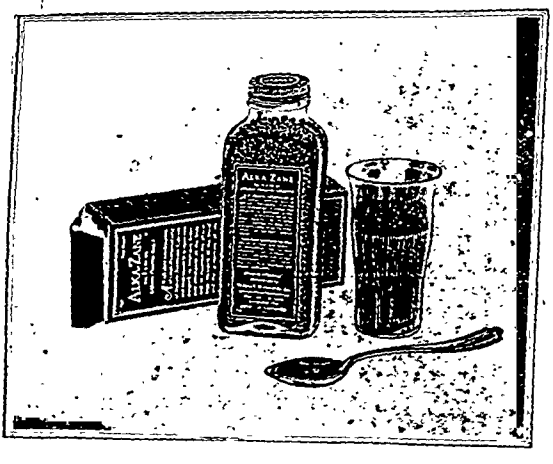
ALKA-ZANE



A pleasant, effervescent granular preparation composed of carefully selected salts of Sodium, Potassium, Calcium and Magnesium in physiologically correct proportions.

is a palatable and rational antacid, indicated in all conditions of relative hyperacidity, rheumatism, gout, intestinal, gastric, and certain cutaneous disorders.

Prompt in action, lasting in effect, it promotes diuresis, neutralizes excess acid production and helps to rebuild the alkaline bases.

The efficiency of Alka-Zane is demonstrable by the briefest of trials.

A supply for clinical use and literature sent gratis to physicians on request.

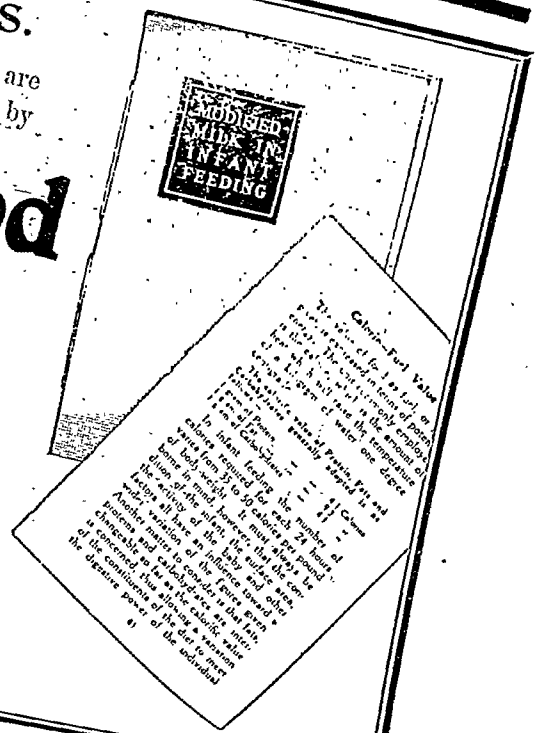
The difficulties that attend hand-rearing are minimised by the use of cow's milk modified by

Mellin's Food

The physical texture of the casein is thereby modified, the carbohydrate constituent raised, and the saline ingredients adjusted; so that the resulting mixture gives most satisfactory results under all average conditions.

Samples and directions for feeding, as well as suggestions for the modification of milk by means of Mellin's Food in cases of malnutrition, diarrhœa, or constipation, will be gladly forwarded by:

MELLIN'S FOOD Ltd., LONDON, S.E.15



Sanatogen Strengthens but does not Irritate

The value of Sanatogen as a tonic food lies in its ready absorption. Even the weakest stomach can easily digest Sanatogen. For this reason Prof. Ewald of Berlin University, amongst others, has frequently given it in typhoid fever and reports that it is promptly absorbed during the febrile period with apparently the same ease as under normal conditions.

Writing in *"The Medical Press and Circular,"* a leading authority says:

"Sanatogen is readily absorbed by the stomach and has an immediate and remarkable effect, shown by a steady increase of body-weight and of muscular strength and energy."

SANATOGEN

CASEIN-SODIUM GLYCEROPHOSPHATE

For Perfect Anæsthesia

More than three years ago, following considerable research on the production of pure ether on a commercial scale, a specially pure brand of anæsthetic ether was issued under the name

ÆTHER PURISS. B.D.H.

As a result of a concession granted by the Commissioners of Customs and Excise, Æther Puriss. B.D.H. was originally manufactured from duty-free rectified spirit to which no methylating agent had been added, and throughout its entire history it has been prepared solely from this source.

Æther Puriss. B.D.H. to-day is of precisely the same quality as it was when first issued, it is now, as it was then, unique on account of its extreme purity.

CONVENIENT AND CLEAN IN USE

MORE CERTAIN IN ITS ACTION THAN THE OLD-FASHIONED POULTICE

The healing action of Regetherm Antiphlogistic Poultice is governed by its ability to prolong and maintain an even degree of heat over a lengthy period. Moreover, the ingredients are so balanced that this action does not set up any counter-irritation, but allays pain, ensures an even circulation through the congested areas, and thus induces natural and pain-free rest.

The Medical Profession will appreciate the fact that the action of Regetherm Poultice is much superior to that of fomentations or linseed poultices, and can be relied upon as an efficient aid in the treatment of all types of inflammation—whether local and superficial, or of deep-seated origin.

Composed of
Ac. Boric., Methyl Salicyl., Ol. Menth. Pip., Thymol, Glycerin, and Kaolin.

Price 2/- per 1 lb. tin

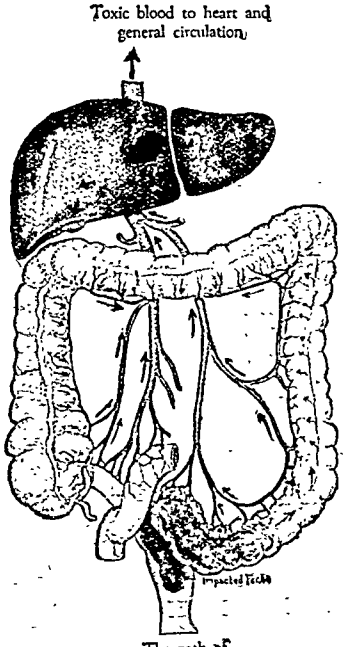
B

Dissolves Intestinal Toxins



The path of Intestinal toxemia

Not the least valuable of its properties is the behaviour of Nujol toward intestinal toxins.

If a watery solution of indol be shaken up with Nujol, more than half the indol is quickly taken up. Nujol readily dissolves this and other waste and poisonous substances, many of which are more soluble in Nujol than in water. Once absorbed in Nujol they cannot be absorbed by the system, as Nujol itself is non-absorbable.

The brownish colour of Nujol as seen in the stool is partly due to toxins which it holds in solution.

Nujol is a safe and effective treatment in all types of constipation and intestinal toxemia.

A doctor's tools must be absolutely sterile. That is why nine doctors out of ten use Marshall's Lysol, which kills every germ and is clear in solution, leaving no desposit upon the instruments

A doctor's hands must touch contagious cases, yet be safe from infection. That is why doctors rinse their hands in Marshall's Lysol, which gives complete safety from infection.

Marshall's is the only Lysol made from the original formula. A doctor who recommends it KNOWS that his patients will obtain a lysol of unvarying strength and quality. That this is vitally important we need not stress. Every doctor and nurse knows that in midwifery, surgery, or cases of infectious disease, the highest grade antiseptic is absolutely necessary.

MARSHALL'S Lysol

LYSOL LIMITED, RAYNES PARK, LONDON, S.W.20. (R)21

OVALTINE

MILK AND ITS DEFICIENCIES.

In the dietary of fevers and infectious diseases milk probably holds the most important position for one reason, that it leaves a residue which is not mechanically irritating.

Milk, however, has certain objections. It is deficient in carbohydrate; it is also repugnant to many people and rapidly becomes tiresome to others.

"Ovaltine" improves milk as a nutritional agent wonderfully. It relieves the monotony of a milk diet. Further, the addition of "Ovaltine" to milk not only makes it more attractive to the taste, but raises the nutritive power and renders the milk twice as digestible—valuable features where dyspepsia is associated with constitutional disturbance.

"Ovaltine" adjusts the carbohydrate deficiency in cow's milk and converts the curd into a light, flaky, easily digested coagulum. It also provides nutriment of inestimable value for maintaining adequate nutrition.

A liberal trial supply will be sent to members of the medical profession in private or hospital practice.

'PANOPEPTON'

WHAT IT CONTAINS.

Contains in solution, in an agreeable form, the entire nutritive constituents of beef and wheat.

Contains all that is digestible in beef—in its juice and in its muscle tissues.

Contains all that is digestible in wheat—its gluten, its carbohydrates.

Contains all the savory and stimulating elements, the extractives, the mineral constituents of beef and wheat.

Contains these constituents in the soluble, perfectly diffusible form into which they are converted in the process of normal digestion.

USES OF 'PANOPEPTON.'

Can be relied upon in cases where the nutrition of the patient is of prime importance.

Has saved the patient in desperate straits due to intolerance of food.

Has nourished and restored in many cases where the patient has steadily lost strength on other foods.

Possesses remarkably restorative and stimulating properties.

Is the most nutritious, the most agreeable and reliable—the BEST of all foods for the sick.

For an adult, the usual portion should be a dessertspoonful to a tablespoonful several times a day and at bedtime.

SUPPLIED IN 12-oz. BOTTLES.

SANDOR FOAM BATHS

Doctors are invited to investigate the benefits now being obtained from the Sandor Foam Baths.

These Baths have for some time been extensively used in the leading Continental Spas, and to cope with the English demand an office has now been opened in London at 55, Pall Mall, S.W.1.

From one complete unit the following classes of Baths can be given:—

1. Air Foam Baths, which are sweating baths of low temperature, *and do not affec the heart.*
2. Oxygen Foam Baths, which are wonderfully cooling and soothing to the nerves, *recommended in cases of Insomnia, Neurasthenia, etc.*
3. Sandor Carbonic Acid Baths, with Foam Cover of greatly increased efficiency, non-poisonous, highly *recommended in cases of heart trouble.*
4. Bubble Baths, which produce an exhilarating effect, *recommended for nervous diseases.*

Full particulars and prices of the SANDOR FOAM BATHS can now be obtained from:—

THE SOAPLESS FOAM CO., 55, PALL MALL, LONDON, S.W. 1

BRAND'S ESSENCE OF BEEF for INVALIDS

has enjoyed the confidence of the medical profession for over 90 years. A nourishing stimulant that demands the least amount of energy in the process of assimilation and increases the means of defence by raising the powers of resistance.

Mark it in your memo book

Brand's essences are scientifically prepared, in jelly form, from the finest English meats, and contain upwards of eleven per cent. of proteid. The nourishing and stimulating properties are IMMEDIATELY ABSORBED, without residue, in the alimentary canal. No time is lost in process of assimilation. No work entailed by the digestive organs. Absolutely pure. Contains no gelatine, colouring, or preservatives. Good for young and old alike.

BRAND'S ESSENCE OF CHICKEN

contains the same nourishing and stimulating properties as Brand's Essence of Beef, and for over 90 years has been recommended by the medical profession when required by prevailing conditions.

Sold by Chemists Everywhere.

Local Anæsthesia in Surgical Practice

CANCER OF BREAST.

Typical Case.

D. H., female, aged 50 years.

Diagnosis: Carcinoma of the right breast.

Operation: Radical excision of the breast.

Anæsthesia: Brachial block, intercostal block, mid-line infiltration; 240 c.c. of 0.7 of 1 per cent. of Novocain-Adrenaline solution.

Operation: Preliminary blocking, the first to the seventh thoracic nerves being blocked. 10 c.c. of the solution were used in the region of each nerve. Brachial anæsthesia, mid-line infiltration. A Wolff graft was used to close the skin defect. In this case the anæsthesia was excellent, although the amount of solution used was comparatively small.

—Extract from PRACTICAL LOCAL ANÆSTHESIA (Farr).

(Full technique of this and one hundred other operations under Local Anæsthesia will be found in above work, published by Henry Kimpton, 263, High Holborn, London, W.C.1.)

THE SAFEST LOCAL ANÆSTHETIC.

Successfully Prescribed in milder cases

The active substances of the extracts from cone-bearing pine trees (Pinus silvestris, Abies alba, Pinus montana) is found in an oily substance commonly known as pine oil.

Novopine Sparkling Pine Bath Tablets contain this oil in a convenient form and an effervescence is introduced to facilitate successful solution in the bath. Their therapeutic value lies in their action on skin, lungs, and heart. For, in addition to the direct action through the pores of the skin, the ozonic aroma given off is automatically inhaled during the taking of a hot bath.

Besides their general cleansing and health giving properties, they have been found especially beneficial as a remedy against nervous heart diseases and kindred disorders.

Samples on request from Natural Products Ltd., 40, Furnival Street, E.C.4.

"SMILER"

THE "JACK SPRATT" CHILD.

"Jack Spratt could eat no fat"

Nervous children, the "Jack Spratts" of the nursery, digest fat badly. This fact has been emphasised recently by such eminent authorities as Still, Cameron & Osman.

Modern conditions of life make great demands on the nervous systems of such children. They are more highly strung, react more readily to emotional stimuli, and this strain is often reflected in digestive difficulties, such as cyclical vomiting, loss of appetite, constipation and bilious attacks.

It has been repeatedly demonstrated that these children cannot tolerate a diet rich in fat, and that whatever fats are to be dealt with must be metabolised in an excess of sugar. An insufficiency of sugar results in the production of ketone bodies and consequently ketosis. An excess of fat is split up in the bowels and neutralised by the valuable calcium and magnesium salts of the milk, which are subsequently excreted in the familiar pale, dry, and crumbling stools.

To meet the needs of this type of infant the manufacturers of "Cow & Gate" Milk Foods have provided a

HALF CREAM

PACKED IN A BLUE TIN

Cow & Gate Milk Food

PACKED IN A BLUE TIN

This food has the following composition:—

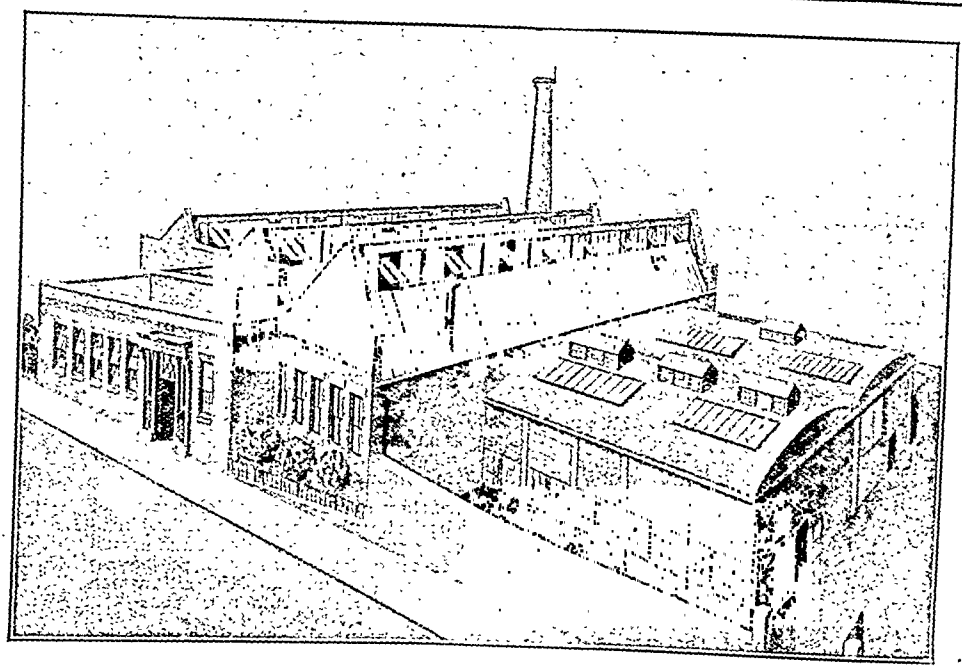
	Dry Food		Reconstituted (1 part in 8 parts of water)
Fat	15.5%	... ...	1.7%
Proteins	20.0%	... ...	2.2%
Lactose	58.0%	... ...	6.4%
Mineral Matter	4.5%	... ...	0.5%
Water	2.0%	... ...	89.2%
	100.0%		100.0%

Half Cream "Cow & Gate" has been used in the large class of "nervous dyspepsias" of infancy with eminently satisfactory results, proving invaluable as a food during periods of fat intolerance so noticeable in the "Jack Spratt" type of infant.

The makers will gladly supply samples and any further information, if required, and wish to remind Members of the Nursing and Medical Professions that the Cow & Gate Laboratories are always at their disposal for experimental work in connection with Milk Foods, and that they will be delighted to arrange visits to their factories in the West of England at any time.

COW & GATE Ltd.,

GUILDFORD.



EVANS' BIOLOGICAL INSTITUTE

The new laboratories at Evans' Biological Institute are now operating, and are a visible indication of the progress this Company is making in the production of Biological Products. As now completed, the laboratories offer both in design and equipment, every facility for the highly technical work which is being carried on there. Broadly speaking, the activities embrace the manufacturing of Sera, Vaccines, Vaccine Lymph, Organo-Therapeutic Products, and the distribution of numerous therapeutic agents for hypodermic medication.

In addition to the manufacture and standardisation of these products, a special department of the Institute's activities is the Pathological Laboratory associated with bacteriological investigations and chemical analyses. At the Institute, also, drugs and preparations manufactured at the Company's Pharmaceutical Laboratories, such as Digitalis, Squills, Ergot and Strophanthus are physiologically tested

A cordial invitation is extended to those who are interested to visit us and examine the work we are doing in greater detail.

BELLE VUE SPA

TEFRIW, NORTH WALES.

(Railway Station: Llanrwst and Tefriw.)

ARTHRITIS.
AMBULATORY TREATMENT.

Mobility and freedom from pain in crippling arthritis of the hip and knee even after shortening and contracture have occurred.

This is the special achievement of BELLE VUE SPA; secured by Hoefftcke's extension appliances, which maintain continuous extension by night and by day.

The appliance permits the patient to walk, and not only takes the body weight but replaces the normal state of compression of the leg by one of active stretching.

There is no other satisfactory way of combining movement with extension.

The method secures:

1. Extension without muscle loss inevitable when the patient is kept in bed.
2. Extension without the vascular stasis which occurs when a joint is kept at rest,

AND

MOVEMENT WITHOUT PAIN.

The result is rapid reconstruction of the joint with astounding restoration of function in those advanced cases which have hitherto seemed hopeless and incurable.

BELLE VUE SPA is well equipped for auxiliary treatment by massage, electricity, diet, light, etc., and full advantage is taken of the tonic virtues of its chalybeate waters.

A Paper
ON
THE DISTRIBUTION AND NATURE OF FOOD POISONING.*

BY
JOHN CRUICKSHANK, M.D.,
PROFESSOR OF BACTERIOLOGY, MARISCHAL COLLEGE, ABERDEEN.

THE subject of bacterial food poisoning presents many features of interest to bacteriologists and practitioners. The sporadic nature of the outbreaks, the dramatic onset of symptoms, and the frequent difficulty of tracing the cause make an unusual appeal to the medical mind. As an additional interest the outbreaks are described in glaring outlines in the daily press, through the medium of which the knowledge of the outbreak is frequently first disseminated. The character of the outbreaks, particularly in their unexpectedness both in time and locality, presents difficulty to the examining bacteriologists, and prevents that continuity of research which is so essential in the investigation of obscure disease. Cases are frequently scattered over a large area, and correlation of the results is correspondingly difficult. Except for the work of a few men, systematic investigations of the etiology of these cases has not been carried out, and as a result the subject presents many unsettled problems.

In opening this discussion I cannot attempt a complete review of the subject, and must content myself with the examination of certain aspects only. To my knowledge there is no new work of special importance to communicate, and it is to be hoped that in the discussion which follows some new information may be given which will throw light on the problems.

It is impossible to approach the subject without an appreciation of the work which has been carried out by Dr. Savage, whose painstaking collection and analysis of outbreaks in this country has added to our knowledge, and whose views, particularly with regard to etiology, will probably serve as the nucleus of this discussion. His interest in the subject and his researches have served to focus the attention of workers in this and other countries upon the whole field of bacterial food poisoning, and constant reference to his work is unavoidable in the course of this paper.

The characteristic features of bacterial food poisoning are the sudden onset of sickness, vomiting, severe diarrhoea, abdominal pain, and pyrexia. The interval between the taking of the infected food and the onset of symptoms is short, varying from two to thirty-six hours. In the majority of cases the severe symptoms persist only for a short time, and within twenty-four hours the patient suffers only from exhaustion. Pyrexia is of short duration, may be absent, and subsides with the severity of the alimentary condition. It is of interest to note that even when the diarrhoea is very severe blood and mucus are rarely found in the stools—a feature of interest in distinguishing these cases from severe dysentery. The extremely short incubation period in some cases has suggested that the symptoms result from the presence of preformed toxins, as it is not in accord with general experience to believe that the viable organisms in the food which is ingested can themselves proliferate within the alimentary canal in sufficient numbers to produce severe reactions in such a short time. In certain outbreaks there is clear evidence that the suspected food has been subjected to such exposure to heat as would ensure the death of all vegetative forms of bacteria. As the signs and symptoms which have occurred in these cases are very similar to those in which live organisms have been demonstrated it has been suggested that heat-resistant toxins are present. This aspect of the subject has recently attracted much attention, and has been examined by experimental work on animals.

Since 1888, when Gärtner described the organism which bears his name as the causative agent in an outbreak of food poisoning, the attention of observers has been concentrated upon the demonstration of this or related organisms in cases of food poisoning associated with the classical symptoms of enteritis. With the development of bacteriological methods and the institution of more intensive examination of such cases, a group of organisms possessing similar morphological and similar, or closely related, biochemical characters has been described of which some members have been concerned in the causation of food poisoning in man or with severe enteritis in animals. The close relationship of these to the paratyphoid organisms has been repeatedly emphasized, and highly technical procedures have been developed in the attempt to differentiate the various members of the group. The general term "paratyphoid-enteritidis" has been applied to this group, although certain workers prefer to use the term "salmonella group," after the hog-cholera organism described by Salmon and Smith. The organism most frequently found is not Gärtner's bacillus, but *B. aertrycke*, an organism very closely allied to *B. paratyphosus* B, and only distinguishable from it by the test of absorption of agglutinins. Since the relationship of this organism to food poisoning has been established its presence in animals closely associated with man has been demonstrated, and the discussion of human food poisoning is closely bound up with the studies of the occurrence of this and related organisms in the intestines of rats, mice, pigs, sheep, and cows.

It may be said that the list of food-poisoning organisms is constantly being extended, largely because of the extension of bacteriological methods of examination to the question of the antigenic structure of bacteria. These methods have proved fruitful in the separation of types hitherto indistinguishable, but have in many ways made the problem of food poisoning more difficult. The work of Sir Frederick Andrewes on the subject of specific and group phases as applied to agglutination reactions, and the great development of cross-agglutination and absorption tests, has not resulted in simplification of the subject, and has made it very difficult for the routine bacteriologist to identify clearly the strain of organism which he may have isolated from a particular outbreak.

Food poisoning has occurred in many countries, and in the general study of these outbreaks it is necessary to take into account the habits of the people as regards food and the general standard of sanitation of the country, particularly with regard to the slaughter of animals and the preparation of food for the table. An important feature of most outbreaks is the apparent soundness of the suspected article, which neither in colour, appearance, nor taste may have seemed to be different from the sound article. This factor has operated adversely in the subsequent examination of the cause of many outbreaks, as it is difficult to secure samples of the suspected food, which has all been consumed. In these cases, unless an organism of the salmonella group can be isolated from the patient's vomit or stools, the cause of the outbreak may remain obscure, although indirect evidence of suggestive character may be obtained by methods such as the examination of the blood of convalescents for the presence of agglutinins for the salmonella group. A very puzzling feature of some outbreaks is the small number of individuals affected, although the infected material—for example, the carcass of an animal—has been widely distributed through a community. In the attempt to explain these outbreaks it has been necessary to suppose either that individual factors of susceptibility play an important part or that the infecting organisms have gained entrance to certain portions of meat through the medium of mice or rats. According to Savage, human carriers, who are so important in the spread of enteric diseases, are not to be regarded as playing an important part in infection, but the possibility cannot be excluded.

A wide variety of foodstuffs has been found to be connected with the outbreaks: tinned meat, salmon, sardines, milk, meat, sausages, pork, mutton, and made-up foods of various kinds. The possibility of infection from eggs has been raised in connexion with a recent case, and Doyle has shown that severe diarrhoea in chickens and ducks may result from infections with *B. aertrycke*. Of these articles the only one which seems to offer conditions suitable for growth of salmonella organisms is milk, and there is

135831

* Read in opening a discussion in the Section of Pathology and Bacteriology at the Annual Meeting of the British Medical Association, Manchester, 1929.

evidence that where milk is the vehicle the outbreaks are widespread and severe in character. In the case of beef, mutton, and pork, suspicion frequently falls upon the animal from which the meat has come, which during life may have been the subject of salmonella infection. The way in which tinned foods such as salmon and sardines become infected is not clear. I am not aware that fish suffer from salmonella infections, and it is necessary to suppose that in the preparation of these foodstuffs, previous to "processing," infection has resulted in the case of individual tins from some unknown source, and that considerable growth of the organisms has occurred with the development of "toxins" which are resistant to subsequent heating.

I have much difficulty in following the chain of reasoning which has been presented as a probable explanation in many outbreaks. It is easy to understand infection of the human subject with living organisms, even though few in numbers, but when these are apparently absent and the outbreak is attributed to heat-resistant poisons an interval for proliferation of the organism and production of sufficent toxin must be postulated. In many of the outbreaks there is no evidence that these conditions are present. It is inconceivable that a few dead organisms in a sample of food can be held responsible for the pronounced symptoms of food poisoning. Experimental work with regard to the ability of salmonellas to grow in various types of foodstuffs at the temperatures at which these are kept would throw light on this aspect of the subject. When the interval between the taking of the food and the onset of symptoms is very short the presence of preformed toxins is suggested as the cause, whereas in the cases with longer incubation period the symptoms are referable to the development in the alimentary canal of viable organisms. It is supposed that both preformed toxin and live organisms may, under certain conditions, be present, and that the symptoms produced by toxins alone may be as severe as those produced by the development of living organisms.

With regard to infection from the meat of animals which have been the subject of salmonella infection during life there is no evidence that their muscular tissues are so heavily infected that after cooking the few organisms present in a small amount of meat could evoke the severe manifestations which occur in food poisoning. It is the opinion of various veterinary workers that the most likely source of infection at the slaughterhouse is from the soiling of meat with intestinal contents. If this is correct, the degree of infection—that is to say the numbers of organisms transferred from an infected animal to other meat—must be extremely small. If we accept the view of Savage that heat-stable poisons from the salmonellas are the cause of these outbreaks, we must suppose that the organisms have developed in large numbers between the death of the animal and exposure to cooking.

The relatively infrequent finding of Gärtner and *B. suipestifer* types is an important feature in the study of these outbreaks, since these types of salmonella appear to be the most frequent exciting agents of disease in cows and pigs. The occurrence of *B. aertrycke* types in the diseases of food animals is extremely uncommon, yet the *B. aertrycke* type is the most common finding in human outbreaks. In the 100 outbreaks recorded by Savage and Bruce White the presence of living *B. aertrycke* was demonstrated in 16 outbreaks, *B. suipestifer* (types Reading and Derby) in 2, and Gärtner only in 1. Many of the outbreaks were investigated in very incomplete fashion, but the absence of living organisms in such a large number of cases would suggest that other causes than salmonella infection should be kept in mind. Unless we suppose that infection of food animals with *B. aertrycke* is more common than has hitherto been shown to be the case infection of the food must have resulted either from human carriers or from contact with animals of the vermin class, particularly mice.

The view strongly advocated by Savage that salmonella infections account for all the cases of food poisoning, with the exception of the few in which chemical poisoning can be shown to be the cause, has led to the concentration of investigation upon the discovery of this group of organisms, with the result that other possible bacterial causes may be missed. In most of the recorded cases there is inadequate data regarding the bacteria present in the food, and in the examination of the stools the presence or absence of salmonella group organisms only has been considered. In the case of dysentery, for example, it has been necessary in recent years to admit to the group of pathogenic organisms the Sonne type of dysentery bacillus, whereas formerly only Flexner and Shiga types were considered in relation to the disease; and it cannot be said that the list of pathogenic organisms in acute disturbances of the alimentary canal is closed when so many cases of diarrhoea, particularly in children, give negative results by the accepted methods of bacteriological investigation.

I would urge strongly a great extension of the bacteriological methods which are employed in the investigation of material which is suspected of connexion with food-poisoning outbreaks and in the examination of dejecta from the sufferers. The close resemblance of the outbreaks in respect to clinical symptoms and signs suggests a single causative agent, but these are not infrequently present in gastro-enteritis from other causes. Savage and others have drawn attention to the importance of existing morbid conditions in determining a fatal issue, and it is worthy of consideration whether other factors may not influence the incidence rate in food-poisoning outbreaks. For example, it has been suggested that the action of chemical reagents used in pickling, such as potassium nitrate, may favour infection by the production of nitrites in the intestine. It is not unlikely that in many individuals the organisms fail to find a lodgement upon the intestinal mucosa, and little or no lesion results, although the intestinal contents contain the infecting organism.

It is remarkable how few cases in any outbreak are attended by a fatal issue, and pathological data from post-mortem examinations are correspondingly meagre. The clinical symptoms point to the upper intestinal tract as the area most affected, and this is in accordance with the findings at necropsy. The severe vomiting and purging must remove much of the unabsorbed toxic material within the alimentary canal, and the rapid recovery in many cases is presumably the beneficial result of these excretory processes. It would be expected that the cases presenting evidence of infection with living organisms would show more prolonged symptoms than in those in which only toxins are present, but in most cases recovery occurs rapidly, and evidence of invasion of the blood stream by organisms is seldom obtained. Nevertheless, the development of agglutinins to salmonella organisms is frequently reported, even in cases in which toxins only are supposed to have been present. As it is the general experience of bacteriologists that it is extremely difficult to produce antibodies in the blood of animals by administering organisms by the alimentary tract, and is only partially successful when enormous doses are given, and frequently only after starvation or in association with the feeding of agents which interfere with normal digestion, this finding of agglutinins in the blood of food-poisoning cases is the more remarkable and worthy of fuller investigation on experimental lines.

The production of agglutinins in the blood is a common occurrence after the "parenteral" injection of living or dead bacteria into the tissues of animals, but their development after a single administration by the mouth seems extremely unlikely. The presence of agglutinins in the blood of cases harbouring viable organisms is to be expected, since the organisms have the power to penetrate the mucosa and enter the deeper tissues. Their presence in the blood seems to me to be an argument against the view that only preformed toxins have been present in the offending food, and to suggest the presence of living organisms, although these may not have been detected in the course of the investigation of the outbreak. Savage and Bruce White, however, record the development of agglutinins in rabbits as a result of feeding boiled cultures of *B. aertrycke*, and Geiger and Meyer after feeding filtrates to mice and to a *Macacus rhesus* monkey. The development of agglutinins in rabbits after repeated injections of extracts of suspected meat in which no living salmonellas could be found has also been used by Savage and Bruce White, and recently also by Pryer, as a means

of demonstrating the nature of the food poisoning. The agglutinating titre of the serums which they have obtained in this way is so low and obtained with such difficulty that the test may be regarded as of little value. The possibility that such injections may merely stimulate the mechanism of agglutinin formation developed in response to a previous natural salmonella infection has apparently not been considered. There is also a lack of important control experiments—namely, the injection of similar extracts made from sound meat into rabbits of the same batch as those under experiment.

Much of the interest in the subject of food poisoning lies in the question of the production of heat-resistant poisons by organisms of the salmonella group. Gärtner in 1888, in his original studies, described the occurrence of lesions in mice after feeding meat previously infected with *B. enteritidis* and cooked for one hour. Of recent years Savage has maintained that *B. aertrycke* possesses potent heat-resistant toxins, and that these are capable of absorption in the stomach and upper intestine of man, giving rise to the phenomena of food poisoning, and that the explanation of many of the outbreaks is to be found in this property. Savage and Bruce White produced experimental results in animals which they believe support this opinion. The enormous numbers of organisms which they used in these feeding experiments produced only slight lesions in experimental animals, and it is impossible to believe that any portion of meat producing meat poisoning in man could contain such numbers. Experimental animals do not appear to be highly susceptible to feeding with salmonella cultures which have been killed by boiling or steaming, and unless we suppose that man is extremely susceptible to small amounts of such toxins these experiments fail to convince.

Other workers have also endeavoured to establish the existence of heat-resistant toxins by animal experiments. Bahr and Dyssegaard, in a recent paper, have investigated a great variety of strains of paratyphoid-Gärtner organisms isolated from a variety of sources, and were able to show that heat-resistant toxins were produced which were capable of producing severe lesions in rabbits, dogs, guinea-pigs, and monkeys, when these were injected into the tissues, but that no effect was produced by feeding even large doses by the mouth. These workers differ from Savage and Bruce White in finding that there was no relation between virulence and toxicity. Dack, Carry, and Hannon, using heat-killed cultures and filtrates of five strains of *B. aertrycke* and four strains of *B. enteritidis*, reported entirely negative results when these were fed to men on an empty stomach, and that no agglutinins had developed in the serum ten days after feeding. The preparations used by these observers were highly toxic to rabbits on intravenous injection. Young cultures of a few hours' incubation were more toxic than older cultures, whereas Bahr and Dyssegaard were of opinion that old cultures (seven to sixteen days) were most toxic. Inconclusive experiments are also reported by Branham, Robey, and Day.

On the other hand, Geiger and Meyer describe the production of a potent toxin with a particular strain of *B. aertrycke* after three to four days' incubation at 37° C. This poison was present in heated whole cultures and in filtrates, and acted by feeding as well as by parenteral injection in white mice. A special medium containing a large amount of protein was used for the cultures. The symptoms occurred within three hours, and death resulted in six to twenty-four hours. Post mortem the duodenal loop was deeply congested and moist, the stomach distended with bile and blood-streaked mucus, and petechia or small erosions were present. The spleen was enlarged, and in some cases the pleural cavities contained blood-tinged fluid. They express the opinion that these post-mortem appearances are pathognomonic for experimental food poisoning in mice. A successful experiment was also obtained with a dose of 10 c.cm. administered to a *Macacus rhesus* monkey, which developed agglutinins to a dilution of 1 in 640 two weeks after feeding. Rabbits, guinea-pigs, and cats usually presented very transitory symptoms. It would appear that mice are the most suitable animals for this type of experiment, but it is remarkable that such difficulties should be encountered in producing toxic manifestations in animals which are frequently the subjects of natural infection with bacterial invasion of the tissues, whereas in man toxic symptoms are prominent and invasion of the tissues rarely found. It is obvious that a comparison of virulence based on the respective weights of the animals concerned is impossible, and that extreme susceptibility of the human species to the action of these toxins must be invoked in order to explain the phenomena.

It would seem a retrograde step to suggest that the difference between the experimental observations in laboratory animals and the results in man may be due to the nature of the medium in which the organisms are growing, as this would raise afresh the question of toxic substances of chemical character. It is, however, worthy of note that many of the food-poisoning outbreaks in man have been associated with tinned foods in which prolonged action of organisms may occur, and that in most of these cases no viable organisms of the salmonella group have been isolated. It is a question for consideration whether in the special circumstances existing in tinned foods these, or other, organisms, may cause the production of toxic substances which have not been obtained in artificial cultures. As the majority of laboratory animals appear to be relatively insusceptible, the experiments, particularly feeding experiments with the suspected meat, should be extended to the monkey, since Geiger and Meyer have reported a successful experiment in this animal with cultures made in a medium of high protein content.

The clinical aspect of food poisoning also presents some interesting material for speculation and investigation. As a result of a survey of epidemics of paratyphoid fever in man Savage and Bruce White have come to the conclusion that the typical signs and symptoms of food poisoning are always absent in this disease. While this is true in most outbreaks, cases are recorded in some outbreaks in which acute symptoms, diarrhoea, sickness, and abdominal pain have occurred immediately after ingestion of the infected food. The number of such cases is small, but I cannot agree with Savage and Bruce White that they may be dismissed as unimportant. For example, in the outbreak of paratyphoid fever recorded by Hamburger and Rosenthal 14 cases with symptoms of acute gastro-enteritis occurred in an outbreak affecting 65 people. Nine of these cases showed pyrexia with general toxic symptoms and intestinal catarrh, and 5 had diarrhoea with slight abdominal disturbance. In some of the cases showing typical enteric fever at a later stage slight pyrexia and vague abdominal signs were present within a few hours of infection, followed by a period of intermission before blood infection and characteristic typhoid infection declared themselves. Hamburger and Rosenthal express the opinion that the cases of gastro-enteritis were those in which little or no infection of the lymphatic tissues occurred, with resulting absence of blood infection.

In other epidemics also a few of such anomalous cases have occurred, and it is open to question whether a rigid separation of food poisoning from paratyphoid fever is justifiable on clinical grounds. Owing to early development of symptoms such cases are apt to make a powerful impression on the clinician, who finds later that enteric fever has apparently been grafted on a food-poisoning outbreak. The pathogenicity of *B. suipestifer* strains for man is generally regarded as low, since it is seldom recorded as the cause of human infections, although Scott has recently reported the occurrence of *B. suipestifer* (Group 2) in a number of outbreaks of food poisoning. On the other hand, cases with signs and symptoms of enteric fever attended by fatal issues have also resulted from infection with organisms of the *B. suipestifer* group, as in the cases recorded by Duncan and recently by Bauer and McClintock. We thus have organisms of closely related type producing symptoms of acute food poisoning, and, exceptionally, prolonged pyrexia of enteric type.

From many points of view the outbreak of food poisoning due to *B. aertrycke* recorded by Perry and Tidy is important. It embraced a large number of cases among our troops in France, and was very thoroughly examined. Although there was no direct proof, the authors were of

way, are not so entirely to blame as one might think. They say what they are taught. When we are told by our own profession that the question of a man's sanity or insanity is one for trial in a law court, just as is the question of his drunkenness or sobriety, I am inclined to feel not only that we shall never get our problem solved, but also that we do not deserve to.

As things are, however, there is no alternative to certification if the voluntary boarder who has become non-volitional is to remain. One practical difficulty immediately presents itself. The patient is certifiable; his relatives wish him to remain where he is, and are content that he be certified. Is it fair to proceed with this and retain him as a certified patient? A majority of the public tell you it is not, and though they might possibly condone it in a non-volitional case, they regard it as a gross breach of faith in the case of a patient who wishes to leave. The patient has to give twenty-four hours' notice of his intended departure, and, although it is perfectly legal, it seems distinctly unfair to use this period in trying to obtain authority to keep a patient who only came upon the condition that he might go when he liked. That, at least, is the way the public look at it, and on the whole I am disposed to agree, although this view ignores the medical aspect and the probability that certification is the best possible thing for the patient in the circumstances. Many mental hospitals go the length of refusing to keep as certified those who have been with them as voluntary boarders, and there is something in this as a gesture, though it is hard to see what principle is involved. Still, it is certainly better than the solemn farce of taking a patient round the town in a cab to two different doctors and a magistrate and bringing him back certified rather than have it said that he was certified on the premises.

It will be convenient at this stage to consider to what extent the voluntary boarder system, with all its drawbacks, is used by the public. It is used to a large and constantly increasing extent. The proportion of voluntary boarders in different hospitals varies somewhat, often in accordance with the tradition of the hospital and the outlook of the superintendent. I have not access at the moment to all the latest figures, but the two hospitals with any considerable admission rate which generally lead the way in this respect are the Bethlem Hospital in London and The Retreat, York. In the latter hospital over 69 per cent. of the admissions in 1928 were voluntary boarders, and I have no doubt that other hospitals had very comparable figures. Now, when seven out of every ten admissions to a hospital for mental diseases which does not pick and choose its cases, but takes everything that comes along, are upon a voluntary basis, there are only two possible conclusions: either certification is largely unnecessary or else it is so distasteful to the public that they will shun and avoid it by every means in their power.

Of course, the process of certification should not be necessary, but it will remain so until we have provided a more satisfactory alternative, and, in particular, until we have solved the problem of the non-volitional case. That it is utterly distasteful to both the lay and medical public there is not the slightest doubt, and it will not surprise me if between them they bring about the practical close of the era of the certified patient in a very short time, quite independently of any change in the law. What the effect of new legislation may be, if and when it comes, I do not know. What I do know is that a large majority of the public regard avoidance of certification as the first and greatest consideration in mental illness. This is, in many ways, a great pity. There is much to be said in favour of certification in many cases, even under the existing law, and most of the public horror of it is the result of ignorance and prejudice. A very able and experienced physician asked me recently why it was that a patient suffering from small-pox or scarlet fever is duly certified and deprived of his liberty as a matter of course without any special legal intervention, public outcry, or social stigma, when the very reverse was the case if it was a question of mental illness. At present we must leave that very pertinent question unanswered, and simply accept the fact that it is so.

People who are resolved to avoid certification of their relatives at all costs will naturally consult physicians who can be relied upon not to advise it, whatever the nature of the case may be. This demand has, of course, been met by a supply of able and devoted ladies and gentlemen with every qualification to be of assistance except a practical training in, and experience of, clinical psychiatry. With their feet firmly—almost ostentatiously—planted on the solid and respectable rock of neurology on the one side, or psychology on the other, they can reach almost incredible distances into the troubled sea of nervous and mental disorder without getting their feet noticeably wet.

Three rather sad things are largely traceable to their activities. First, if the case becomes so acute or so obviously psychotic that mental hospital care becomes urgently necessary, the relatives are almost inevitably given the impression that the case is hopeless, that treatment has failed, and that all that remains is for the patient to be "put away," the mysterious and awful doom of "lunacy" having fallen upon him. Secondly, and arising out of the above, the most fantastically absurd and untrue ideas with regard to mental disorder, certification, and mental hospitals are of necessity absorbed by the public and perpetuated amongst them. Finally, and most serious of all, many patients are deprived—from the best motives—of what would be the ideal treatment for them.

The public horror is not merely of certification *per se*: it is even more of what they call the "asylum atmosphere." They could perhaps stand their relative being certified, but what they cannot bear is the thought of him "associating with lunatics." This is so well recognized that we need not go into it at length, though one is tempted to do so. On the very day I wrote these words I saw a patient sitting alone, silent, unoccupied, slowly dementing, and "tenderly neglected" in a comfortable room in a privately owned mental hospital because her relatives have insisted that she shall not in any circumstances "associate with lunatics." Much of the agony—there is no other word—through which the relatives of patients pass in this matter is the result of ignorance and prejudice alone. There are few things of which I should less like to feel guilty than of having—for any reason—done anything to perpetuate that ignorance or foster that prejudice.

This dread of "asylums," as apart from the mere process of certification, is, of course, what affects the intending voluntary boarder, though to a much less degree, strangely enough, than it does the relatives of the certified patient. The point I must go on to make, however, is that in either case a certain amount of this dread of "asylum atmosphere" is to some little extent well founded, though the public are far from realizing the real nature of the trouble. It is the old question of "grading" which is at the bottom of it all. The extraordinary variety in the symptoms and needs of the patients admitted to a mental hospital of any size, along with the constant dead weight of irrecoverable chronic cases, present a problem which needs—among many other things—almost unlimited space, staff, and money for its solution. Only those familiar with mental hospital work can appreciate the difficulties of the situation which is made the excuse for criticisms which are often peculiarly irritating, fallacious, and unjust. For some years I have been convinced that this difficulty is being met in the wrong way—namely, by keeping mild cases away from the mental hospital, which, with all its drawbacks, is, as I have said, infinitely the best place for them. It is more than that—it is the only place where they can obtain the understanding management, the expert treatment, and, above all, the skilled nursing care, which are their greatest needs.

I have long thought that we should begin at the other end, and remove to completely separate and independent branches of the mental hospital the chronic, unpleasant, and noisy cases. It would need more than two separate establishments to do the thing ideally, and of course the branches, though entirely separate, would have to be near enough for quick and easy interchange of patients. To my great delight a scheme of the kind is actually in preparation in London just now, the pioneers being the governors of St. Luke's Hospital. When completed, the reorganized St. Luke's will consist of three separate establishments, one in London and two near it—one of them for quiet, recent, co-operating patients; the second for

noisy and troublesome acute cases and irrecoverable chronic ones; and the third for convalescents. Best of all, there is a fourth branch, in some ways the main and central one—namely, an out-patient department and a ward for in-patients at a great general hospital, the Middlesex.

I mention this scheme not to discuss it, but to show what can be and is being done in the face of quite extraordinary difficulties. I am glad to think that it is one of the registered hospitals which has taken the lead in this way, and I hope that under its enlightened and far-seeing head, Dr. Gilmour, the new St. Luke's will have the success which it deserves.

I have felt the responsibility and the difficulty of preparing this paper very keenly. I have left unsaid a great deal that might well have been included in our subject, but the whole matter is such a far-reaching one that if discussion is to be fruitful we must limit its range.

I have therefore—here and there with reluctance—touched upon the points which seem to me most to need frank and courageous discussion. And I want our discussion to be fruitful. There is so much to do, and there are so many difficulties in the way. But it is to the general body of the profession that we may fairly look for help. There could be no better outlet for the organized activity of the profession and of this Association than a combined effort to bring just a little more science, a little broader humanity, a little more practical good sense, into our dealings with sufferers from the saddest of all human ills.

THE X-RAY TREATMENT OF WOUNDS.*

BY

PROFESSOR DR. LEOPOLD FREUND,

VIENNA.

IT is the experience of many of the older radiologists that the healing, not only of carcinomatous, sarcomatous, actinomycotic, venereal, tuberculous, and other ulcers, but also of old, neglected, sluggish, or badly healing wounds, can be hastened by the influence of x rays. This agrees with the experience of those authors who used the sun's rays, or powerful sources of artificial light, for the same purpose. It was the observation of the effect of light on an old wound, the result of a stab with a knife, which induced our distinguished colleague, Dr. Bernhard of St. Moritz, to introduce the sun's rays as a healing factor into therapy in the year 1902.

It is difficult to decide whether this beneficial influence is due to the stimulating effect of small doses of x rays on the functions and growth of the cells, or whether it is to be traced back to the elimination by x rays of an antagonistic factor which delays cicatrization. In my opinion, which is also shared by Professor Arzt and Dr. Fuhs, the question whether the increase in proliferation is caused by direct or indirect stimulation of the activity of the cells is of less importance, for all practical purposes, than the fact that undoubtedly small doses of x rays have a stimulating effect on badly healing wounds.

But it is not this subject, interesting and of practical importance though it certainly is, to which I wish to direct your consideration. I desire to solicit your interest for one particular indication for x rays, which would appear to be little appreciated in your country—the x-ray treatment of fresh and open wounds. As long ago as 1898 I noticed the beneficial influence of x rays on keloids and bad scars. In a later histological experiment on a very large keloidal scar, I observed that the hyperplasia of the connective tissue arose from the numerous young round cells and spindle cells clustered round the blood vessels. The idea at once occurred to me that it might be possible to prevent the formation of keloid by exposing to the destroying influence of x rays those groups of cells which, on account of their youth, are particularly sensitive. Since then, after complete excision of tumours in a number of people who showed a tendency to keloid formation, instead of stitching up the wounds or covering them with skin grafts, I administered small doses of x rays to the open wounds, the bleeding of which had been stopped *lege artis*. The x-ray dose was administered immediately and repeated on several successive days; without exception very good results were obtained. As a consequence I did not hesitate to employ this method in other pathological conditions for which I considered it suitable; in this work I have enjoyed the valued collaboration of Professor H. Salzer.

The following conditions were treated: circumscribed patches of lupus vulgaris, epitheliomata, rodent ulcers, keloids, and pigmented naevi.

This method offers various advantages over other methods of treatment of lupus vulgaris and malignant new growths. When such pathological masses of tissue are excised the x rays do not have to destroy these tissues, a task which they cannot accomplish as quickly as a knife. Masses of tissue of varying thicknesses are removed, which would otherwise weaken the rays by absorbing them on their way to the base of the lesion. Thus the x-raying of the open wound after operation renders the operation more effective. If some traces of the disease are left in the wound, they will be attacked more intensively than when the wound is stitched up. If, in spite of excision and subsequent treatment with x rays, some remaining trace of the disease gives rise to a circumscribed recurrence, this may be removed easily and quickly by the same method. The thin delicate soft scar offers only a slight resistance to the breaking through of the new growth to the outside. This constitutes a very important advantage over large wounds which have been stitched or grafted. Such wounds often become so hard, thick, and oedematous that they offer insuperable obstacles to the breaking through of the infiltration which is growing beneath them, and which consequently takes the line of least resistance and spreads beneath the scar. In other words, a thick scar encourages the propagation of the disease in the body of the patient.

As the cosmetic results are excellent, the resulting scars being not inferior to those obtained with Finsen light, we used this method in a large pigmented naevus, in which excision with subsequent stitching or Thiersch grafting, would certainly not have given such a good cosmetic result as that which we obtained.

The method offers, in addition, in lupus vulgaris and malignant processes, the great advantage of shortening considerably the duration of treatment, especially that of the required x-ray treatment. For instance, in lupus vulgaris it dispenses with the frequent application of x rays, which would be necessary if the lesion were not previously excised, and we have all had experience of the dangers which may result from continued x-ray treatment. By using my method a patch of lupus vulgaris the size of the palm of the hand can be fully healed in six to eight weeks.

The application of this method has its limits, depending upon the localization and extent of the lesion; within these limits there still remains a wide scope for fruitful work.

Wounds in situations where the skin remains stretched are the most suitable for this kind of treatment. Near joints or folds, where the edges of the wounds approach one another whilst in movement, the resulting scars are only satisfactory if movement is eliminated by a firm bandage during the period of healing. Even a very extensive wound following excision is not an obstacle to the formation of a good scar. For instance, I saw a circular wound with a diameter of 10 cm. over the great trochanter, which resulted in a perfect scar. According to my experience the duration of healing of wounds after x rays is certainly not longer than it would be without x rays.

As a result of an experiment on an animal which I performed with Dr. Peach of Manchester during her stay in Vienna, we found that a fresh wound x-rayed with our therapeutic dose was healed a little earlier than an un-x-rayed wound of exactly the same area and depth, symmetrically situated in the same animal. This observation was recently confirmed by a communication from H. Suichi Fukase of the Holzknecht Laboratory.[1]

Herr Glocker found that wounds healed more slowly after x rays; probably this was due to the dosage given.[2] The dose which we usually apply is a little higher than an

* A paper given by invitation at the Annual Meeting of the British Medical Association in Manchester, July, 1929.

epilation dose, about 6 to 7 H. We distribute it over six or seven sittings, which take place at intervals of two to three days. It would appear that unfiltered rays of 6 to 7 H. hardness are more efficient than strongly filtered hard rays.

We may note in passing that Popoff and Teskoff, experimenting on the hastening of the regeneration of wounds, found that $MgCl_2$ was especially efficient, particularly at intervals of one to two days.[3]

Cases where the lesion is situated in folds or angles of the skin are not suitable for this method—for example, at the upper end of the naso-labial folds, near the alae of the nose, in the angle behind the lobes of the ears, and similar situations. After the excision of such a lesion a cavernous wound results, the inner surface of which cannot be reached in its entire extent by the *x* rays. Very extensive lesions are also unsuitable.

Herr Franz Freund recommends the previous *x*-raying of wounds (*loco citato*), because, in his opinion, the beneficial effects of *x* rays on fresh wounds is due to the fact that they hinder inflammation and the development of the exudation of leucocytes. But I cannot see that this proposal would improve my method, because I consider it a somewhat doubtful procedure to operate on an area of the skin which has been *x*-rayed shortly beforehand, as such a skin sometimes reacts to every form of trauma with an *x*-ray dermatitis. Further, I do not consider it reasonable previously to *x*-ray a portion of skin which is to be immediately excised.

Bearing on this point the communication of Richard Sparmanns is noteworthy.[4] He states that in Malays, who have a very strong tendency to excessive hyperplasia of the connective tissue, and who are liable to keloid formation, the prophylactic *x*-raying of the area before the operation, or *x*-raying immediately after the removal of the stitches (that is, where the open wound is not *x*-rayed), is very often useless.

In conclusion, I thank you for the honour which your Association has done me by its kind invitation, and I am very sorry that it is impossible for me personally to be present. I am very grateful to my eminent colleague and old friend, Dr. Lancashire, for delivering this paper in my absence.

THE CAUSES AND TREATMENT OF PERSISTENT NASAL CATARRH, PARTICULARLY IN CHILDREN.*

BY

DAN McKENZIE, M.D., F.R.C.S.ED.,

SURGEON, CENTRAL LONDON THROAT AND EAR HOSPITAL.

THE term "nasal catarrh" has of late years become a popular expression covering a large variety of pathological processes. It differs from that other popular disease "a cold in the head" in being chronic, although to be sure nasal catarrh may start with a cold in the head, and its course [illegible] ated by recurrent bouts of the same [illegible] this into medical phraseology we may say that a cold in the head is an acute rhinitis, and nasal catarrh a chronic rhinitis, both being characterized by a discharge of mucus or muco-pus from the nose, and by inflammatory swelling of the turbinals, particularly of the inferior, leading to nasal obstruction. In the acute disease the symptoms are more severe, and the headache, malaise, and muscular languor betoken the presence of toxaemia. It is, besides, an infectious disease; at least in certain circumstances it behaves as such. (Paroxysmal rhinorrhoea is, of course, out of bounds in the present discussion. It is not nasal catarrh, although popularly it goes by that name.)

Rhinitis, whether acute or chronic, is due to an infection of the nasal mucosa. But when we ask by what micro-organism it is induced we are presented with an embarrassment of riches, since almost any of the *pyogenes* may be present, alone or in company. But inasmuch as the pneumococcus is the most constant, it is natural to infer that that organism is probably the pioneer of the invaders. The fact, however, that during the early hours of an acute catarrh the nasal secretion contains but few bacteria of any kind has led to the surmise that the first onslaught is made by an ultramicroscopic organism, and that those usually found present are secondary infections.

From the clinical, as distinct from the bacteriological, point of view, we may divide our cases into two groups: first, those in which the catarrh can be traced to a local cause or focus; and secondly, those in which no such local cause can be detected.

The chief local causes in children are, first and foremost, adenoids, with or without hypertrophied inferior turbinals and tonsils, and, secondly, nasal sinus suppuration. In adults the same local causes exist, although with a different relative frequency, sinus suppuration being more, and adenoids less, common than in children, while, in addition, deviations of the nasal septum lead on to nasal catarrh frequently in adults and seldom in children.

Our discussion refers particularly to nasal catarrh in children, and at once the mind turns to the all-important if well-worn subject of adenoids.

What is the relationship between nasal catarrh and adenoids? Are they both expressions of one and the same infection? Or does the one induce the other? And, if so, which is the primary? Here we find ourselves up against the old but still unsolved problem of the cause of adenoids. In endeavouring to find a way out of this maze of questions all we have to guide us, as far as I know, is clinical observation. Bacteriology is silent, and experimental pathology is not very helpful. But let us see what we can gather from our observation of the disease.

First of all, I have been informed by Dr. Alice Vance Knox, who has a large experience of welfare work, that nasal catarrh is one of the earliest of life's maladies, appearing quite frequently in infants only a fortnight old; and the same observation has been made by R. C. Clarke, who remarks also that the nasal catarrh is always associated in infants with bronchial catarrh. Now it is well known that lymphoid tissue can be demonstrated in the nasopharynx at birth, but it is rarely bulky enough to require removal until months, and more often years, later. This seems to indicate that the catarrhal infection of the nose precedes the pathological hypertrophy of the lymphoid masses.

It will be remembered also how Dr. P. Watson-Williams has suggested that adenoids are due to chronic bacterial infection of the nose. In criticism of this view we sometimes hear it said that lymphoid hypertrophy as a reaction to sepsis is a novel, hitherto unknown phenomenon. But it is by no means novel or unknown. What is the nature of the enlarged cervical glands that accompany chronic hypertrophy of the pharyngeal tonsils? The members of the whole group of enlarged lymphoid aggregations—adenoids, tonsils, and lymphatic glands—are quite obviously related to each other and to some low form of chronic sepsis, located in themselves no doubt. But from what primary source did it emanate if not from the nose? Thus, according to this view, adenoids is merely an incident in the course of chronic rhinitis.

But, attractive though this explanation may be, it does not account for all the phenomena. If chronic nasal sepsis can in this way induce hypertrophy of the nasopharyngeal tonsil, why are not adenoids also produced in adults with chronic nasal catarrh? We cannot answer this question except by assuming that there is no lymphoid tissue to undergo hypertrophy in the nasopharynx of adults—and that is not the case.

In children adenoids sometimes recur after they have been quite efficiently removed. Their cause must therefore be persisting. Again, is it chronic rhinitis? But once more, what is the explanation of their non-recurrence in adults after removal?

* Read in opening a discussion in the Section of Oto-Rhino-Laryngology at the Annual Meeting of the British Medical Association, Manchester, 1929.

As we all know, however, recurrence of adenoids in children after removal is not common, and their removal is usually followed by cure of the nasal catarrh. Probably, however, this does not mean that the adenoids had been responsible for the nasal disease, but merely that both of these disturbances had been initiated by a common infection, which the bodily resistance, heightened by the improved health that follows the operation, is able to throw off completely and permanently. What interests us to-day, however, is the exceptional happening—the persistence of nasal catarrh after removal of adenoids. This disappointment we have all experienced, when, in spite of a complete clearance of the nasopharynx, the little patient still keeps on "catching cold" at frequent intervals.

Nay! Quite often nowadays we see acute suppuration of the middle ear with mastoiditis in children who have had their adenoids removed, and whose nasopharynx is smooth. I have sometimes wondered whether, in such cases, the nasopharynx is not rather too smooth and hard, lined as it is with scar tissue; whether, that is to say, when operating for adenoids, we are not sometimes a little too thorough in our curetting. To substitute scar tissue for mucous membrane is scarcely an improvement upon Nature. This consideration has always seemed to me to be one of the points in favour of the sliding adenotome.

To return to our main theme. When nasal catarrh persists after adenoids, and perhaps also tonsils, have been removed, there are, in children, two further possible causes, which may, of course, be combined—namely, enlarged posterior ends of the inferior turbinals, and nasal sinus suppuration.

With regard to the former, the late Mark Hovell used to insist upon removing "posterior ends" at all adenoid operations. Without going quite as far as that, perhaps, we should nevertheless always examine for them at the operation, and then if they are much enlarged they should certainly be got rid of. If they are only slightly swollen they may be left, as they will probably subside with the general improvement in local conditions. If they do not shrink, however, they maintain the symptoms of nasal catarrh, giving rise to obstruction of a peculiarly variable character.

Sinusitis we have long known to be one of the common causes of nasal catarrh in adults, but it is only within the last few years that its importance in children has come to be realized. It is, of course, much less frequent in childhood—at least it is less frequently discovered. It also runs a more acute course in early life. The sinuses in childhood are relatively small; some of them—the sphenoidals, for example—amounting to little more than tiny cells, while the frontals do not begin to develop until the seventh year. So it is the ethmoids and maxillary antra that are of most importance in children, and they are frequently, if transiently, affected during colds in the head. If the surgeon makes a practice of washing out the maxillary antra in children with mastoid suppuration, as Watson-Williams advises, he will be surprised at the frequency with which he will find pus in the washings. In these conditions a single washing-out is usually sufficient to cure the nasal infection, and the ear infection also benefits.

In the ordinary way, and apart from ear complications, chronic nasal catarrh in children, adenoids and posterior ends having been excluded, should lead to an examination of the ethmoidal region and of the maxillary antra. In so doing we must remember that neither transillumination nor *x*-ray examination are of much value in childhood; negative findings, at all events, should always be doubted. For the antra, proof-puncture under general anaesthesia is alone reliable, the needle being inserted close above and not below the inferior turbinal, as the floor of the antrum is relatively high in early life. If simple lavage fails to cure the antrum suppuration, a nasal antrostomy opening may be made with a small burr or rasp. Operation through the canine fossa, however, is not recommended prior to the eruption of the permanent teeth.

One question in connexion with nasal catarrh and sinusitis in children I should like to hear your opinion upon, and that is: Is it possible that obstinate sinusitis and polypus formation in young adults is a development of nasal trouble, apart from adenoids, that begins in childhood?

The last local abnormality causing nasal catarrh I shall allude to is deviation of the nasal septum, a source of trouble much less common in children than in adults. We do meet with it, however, from time to time, as a result of a traumatism, and the surgeon may have to decide whether to operate at the risk of stunting the growth of the nose. In such a case the general condition of the paient must be the deciding factor. If the nasal obstruction and catarrh are interfering with the child's normal development, the risk should be accepted and the operation performed. I am sure I do not need to remind you that the septum operation in a child entails a peculiarly difficult and delicate manipulation. But if the septal deformity is not obviously interfering with nasal breathing the operation should be postponed until after puberty.

In adults nasal catarrh, with its consequent hypertrophies, is frequently enough the result of septal deviation, and will be materially benefited by the submucous resection and by removal of obstructing redundancies. But the operation should be strictly limited to cases which obviously require it, for I fear that there is a tendency among some rhinologists to perform submucous resection rather too readily.

Such are the local causes of nasal catarrh particularly in children, together with some of the means at our disposal for dealing with them. It may happen, however—indeed it frequently does happen—that, even after all the measures for eradicating the trouble have been adopted, the case fails to respond; the "colds" keep on recurring; and the nasal catarrh, though perhaps milder, does not entirely disappear. Or, to take the other possibility, the patient may manifest no sign of any local abnormality whatever to account for his catarrhal symptoms—apart, perhaps, from the turgescence of his turbinals, which is, of course, more likely to be the effect than the cause of his trouble. And what are we to do then?

The point is that, while a septic focus such as adenoids or an infected sinus—themselves by the way the product frequently of acute catarrh—will favour the persistence or the frequent recurrence of the catarrhal infection, clinical experience teaches us that there are people, both young and old, who, without any discoverable abnormality whatever, are nevertheless peculiarly susceptible to this infection, and what we are interested in is how to reduce or abolish this susceptibility. And the interest is one we share with mankind in general, for what we are about to discuss now is the prevention of that universal plague known as a cold in the head; acute coryza; acute epidemic catarrh.

The first question to be answered is: Is the practically universal belief that acute nasal catarrh is due to cold, to chilling of the body surface, right or wrong?

In the first flush of bacteriological enthusiasm, most of us—I plead guilty myself to the charge—denied that this was anything but a superstition, and we pointed triumphantly to the plain evidence of infection from one person to another. But longer experience, observation, and cogitation have modified our opinion to this extent—that we have regard now to the soil as well as to the seed; and so we no longer contemptuously reject the belief that exposure to cold, particularly in the case of sedentary, indoor people, will predispose to and often actually precipitate an attack.

The process of inception, however, is not quite simple. Apparently what happens is that most of us pass through an acute attack every six months or thereabouts—that is to say, we acquire an immunity that keeps the infection at bay for about six months. If we are able to lead a healthy life and are not exposed to extremes of temperature or fatigue we go the full period. But when we are nearing the limit of our period of resistance, exposure to cold—a wetting, falling asleep in a draught, a bitter east wind—is sufficient to push us over the edge, so to speak.

Moreover, there are among us people who "catch cold" more frequently than their neighbours. Most of them, but not all, will be found to have one or other of the septic foci mentioned above. Whether or no, the suggestion may be advanced that these people are "carriers" of the virus, and very prone to auto-infection and to the heightening in virulence of the infective agent to such a degree that during the acute stage it can pass from one person to another. Thus the general population, the majority of whom are presumably not themselves carriers, is periodically exposed to infection from a large number of centres simultaneously. Indeed, the well-known appearance of a pandemic in England every spring and autumn can best be explained by the concurrence of attacks in carriers susceptible of meteorological influences, and transmitted by them to a populace whose resistance is low.

To put the matter in a nutshell, a susceptible person or child—often a sufferer from chronic nasal catarrh—develops acute catarrh spontaneously, and proceeds to infect his healthy neighbours; and exposure, fatigue, malnutrition, like any debilitating circumstance, favour the onset of the disease, both in the susceptible and in the more resistant, but they are not indispensable factors in the causation.

The treatment of nasal catarrh, of the chronic as well as of the acute variety, is dictated by our views upon its etiology. You and I, as rhinologists, deal with local causes, as outlined above, sometimes with success, sometimes not. Secondly, bacteriologists, convinced of the evil wrought by bacteria, seek to maintain the patient's resistance at a high level by the administration of vaccines, with, I am afraid, not invariable success. Sometimes a course of vaccines will be followed by a year of freedom from acute attacks. At other times an acute attack will set in a week or two after the course of vaccines is concluded. Nevertheless, a course of vaccines twice a year in susceptible people is a simple, harmless procedure, which every now and then is followed by a prolonged intermission. Let us, however, again utter the warning that not even the most potent vaccine will remove nasal polypi. In other words, always look out for and remove local causes as a preliminary.

But at the same time as the specialists are trying their luck, the general physician, the general practitioner, and the general public as well, are all equally busy with their methods of treatment, with the result that the patient is subjected to a bewildering shower of remedies, all of them successful, for a cold in the head gets well of its own accord until the next time. There is, indeed, no practical method of preventing this contagious disease, and there is no specific cure. All we can do is to remove, when possible, all local sources of sepsis and irritation, and to build up and maintain a high resistance against the coryza-producing virus, whatever it may be, by sensible hygienic measures, both personal and communal.

In this connexion we ought perhaps, in our capacity as rhinological experts, to express some sort of opinion upon certain therapeutic counsels that have, of recent times, become very prevalent, if not very popular.

In the first place, we are often advised, if we wish to keep ourselves free from infection, to sniff every day various chemical solutions up the nose. By the way, I am not acquainted with any rhinologist who follows this ritual himself. Perhaps for the very good reason that it is probably quite ineffective and certainly not free from danger. I have known an acute otitis media result from this insult to the upper air passages.

Again, we have to encounter the cold-water, open-air crank, who puts down all the ills that flesh is heir to, and specifically nasal catarrh, to living and working indoors. But this is the twentieth century. Few of us can afford to revert to savagery, and, if we did, how long could we keep it up here in England without developing an acute antrum? Yet these exuberant Bohemians, not content with their own virulently ascetic practices, inflict them also upon their children; and you will see their long and skinny daughters, with red-rimmed eyes and weeping noses, sent out to face a Kingsley's nor'-easter, nude and purple from the ankles to the nates. No one will ever persuade me that that regimen is either safe or sensible—or even decent.

As a matter of fact, this hardening process is not modern. It is very ancient, having been in vogue for something like 2,000 years to our knowledge. Listen to the orations of Aristides—not Aristides the Just, I may say.

"His health," he tells us, "was bad about the time of the winter solstice. It was a stormy day. The god ordered him to rub himself over with mud, and run three times round the Temple. It was a north wind and keen frost. He did as Asklepios ordered, then bathed at the well, and felt fine. . . . But—a companion who imitated him had a paralytic spasm and could scarcely be restored to heat."

Is it asking too much of them to beseech our open-air faddists as they are strong to be merciful, remembering that most of us are but a feeble folk, who, after exposure to rigorous cold, do not experience a warm vasomotor reaction, but, like the companion of Aristides, fall therefrom into a "paralytic spasm," and can "scarcely be restored to heat."

Finally, there are those who go to the opposite extreme, and, wrapping garment after garment around themselves and their children until they have as many coats as an onion, live in a continual bath of perspiration. Rendering themselves thus sensitive to every breath of air they fear a draught as they should the devil, and no wonder, for a current of fresh air is to such people, with their soppy skins and flabby circulation, a real source of discomfort and even at times of danger.

After all, we all know quite well the golden rule of health in these matters. Let us seek the *via media*, and expose our system to extremes of no kind, neither over-coddling nor overtaxing our bodies. By that means we shall obtain the best results—save, to be sure, in the daily press, for this kind of advice is much too quiet and sensible to furnish our journalists and our journalistic medical geniuses with the excitable headings their souls hanker after.

THE INCIDENCE OF TUBERCULOUS INFECTION IN THE MILK SUPPLIES OF SCOTTISH CITIES.

BY

NORMAN C. WRIGHT, M.A., PH.D.

(From the Hannah Dairy Research Institute, The University, Glasgow)

For a number of years attention has been directed to the danger of the milk supply as a potential source of infection of the population with bovine tuberculosis. The report of the Royal Commission on Tuberculosis drew attention to the need for adequate control of the milk supply by local health authorities, and since the issue of that report considerable improvements have been effected, both by legislation and by voluntary efforts on the part of individual milk producers. The increased control of city milk supplies by more frequent periodical tests, the Tuberculosis Order (by which local authorities have the power to inspect all cows which are giving milk for public consumption, and to order the slaughter of those which are either excreting tubercle bacilli in their milk or are in an advanced stage of the disease), and the voluntary establishment of tuberculin-tested herds by individual owners, all tend towards ensuring a decreased incidence of infection in the milk supplied to the large centres of population.

During the last few months considerable attention has been devoted in the public press and elsewhere to the potential danger of the milk supply, and somewhat indiscriminate statements have been made as to the actual extent of the tuberculous infection of milk. Unfortunately no collected data of the present position with regard to infection appears to be available, and, in order to fill this gap in our collected knowledge, an attempt has been made to put together such relevant information as is available with regard to the milk supply of Scotland.

An examination of the older literature reveals the following series of figures, most of which were obtained prior to 1914.

TABLE I.

Locality.	Authority.	Percentage of Infected Milk.
London	Medical officer of health	9.9
Manchester	Delépine	8.7
Edinburgh	Miller and Mitchell	16 to 20
New York	Grund and Wilcox	11.5
Philadelphia	Campbell	13.8*
Four cities, U.S.A.	Lochead	8.3
General results, U.S.A. ...	Lochead	6.7 to 19.5

*13.8 per cent. sold as raw milk; 8.3 per cent. sold as pasteurized milk.

These figures, while showing considerable divergence from one another, all point to the very considerable infection of the city milk supplies examined by these various authorities.

In the present survey an analysis has been made of the infection of the milk supplies of Edinburgh, Glasgow, and Aberdeen, as evidenced by the data available in the reports of the medical officers of health of these cities, and by personal inquiry from the officials.*

It should be emphasized here that the figures quoted refer only to samples of *raw* milk. Actually a considerable proportion of the milk supply—in Glasgow as much as 80 per cent.—is pasteurized before delivery to the consumer, and the risk of infection will be very considerably reduced. Further reference to this point will be made later.

Tuberculous Infection of City Milk Supplies.

In collecting the figures from the various reports, only those which referred to infection as determined by biological (inoculation) tests were included, since microscopic tests are at best only a very rough guide to the presence of tubercle bacilli.

In the first instance the collection of data was limited to the infection of samples of mixed milk received from country sources. It was at once found that the year-to-year variations were so great as to nullify entirely any direct yearly comparisons between the different cities, owing to the comparatively small number of samples tested each year. For instance, the results for Edinburgh for each of ten successive years were found to be 8.5, 9.3, 9.9, 11.6, 2.2. 5.3, 14.0, 8.1, 10.9, and 5.7 per cent. It was therefore found necessary to take an average of the results over an extended number of years, and in this way it was possible to obtain figures which were of definite significance. These figures are summarized in Table II.

TABLE II.—*Tuberculous Infection of City Milk Supplies.*
(Samples of mixed (raw) milk taken from bulk on arrival by transport from country sources.)

City.	Years.	No. of Samples Examined.	No. of Samples Infected.	Percentage of Samples Infected.
Edinburgh ...	1918-1927	795	67	8.5
Glasgow	1921-1927	1,083	28	2.6
Aberdeen ...	1922-1927	1,205	66	5.5

It will be seen that the difference between the percentage of infected samples in each of the three cities—Edinburgh, Glasgow, and Aberdeen—is most striking. The question was at once raised as to how far the results obtained during the periods examined were true indications of the average infection of the whole of the milk supply of each city. Further information was therefore sought in order to determine (*a*) how far the results at each centre agreed with those obtained in previous years, and (*b*) how far the possible variations in the technique of the test at each centre might render the results incomparable.

*No other Scottish cities have sufficient data for comparison.

With regard to the first point the following facts were ascertained. The Edinburgh results agree fairly well with those previously obtained in this city by other workers; they are, in fact, on the whole lower than those previously published. For the years 1905 to 1914 the percentage of infected samples in the Aberdeen supply was 5.9, a total of 289 samples being examined during this period. This percentage agrees closely with that shown in Table II. The number of tests carried out at Glasgow since 1908 has been considerable, and a summary of the tests is given in Table III. The results of these tests show good agreement among themselves. It would be expected that the lowest incidence of infection would be found in the samples from individual cows (mostly taken in attempting to trace cows responsible for the infection of mixed milk samples), that the milk of cows with udder disease would show a higher percentage of infection, and that the highest figures would be obtained from mixed milk samples, where the milk of a number of cows is bulked. The collected results shown in Table III bear out these points. Further, the general results of the tests are of the same order, and the two mixed milk results (3 per cent. and 2.6 per cent. respectively) show good agreement.

It appears, therefore, that at all three centres there is sufficient evidence to show that the results represent a true average of the normal infection of each city's milk supply.

TABLE III.—*Glasgow Milk Supply.*

Details of Samples.	Years.	No. of Samples Examined.	No. of Samples Infected.	Percentage of Samples Infected.
Samples from cows with disease of the udder	1903-13 1921-27	3,384 2,173	84 32	2.5 1.5
Samples from cows supplying hospitals	1908-13 1921-26	413 3,014	5 17	1.2 0.56
Mixed milk supplied to hospitals	1921-26	923	28	3.0
Mixed milk of city (see Table II)	1921-27	1,083	28	2.6

We have therefore to turn to the second point—namely, to ascertain whether the variations in the results can be attributed to differences in technique in testing the milk samples. By the courtesy of the officials concerned I have been provided with the details of the technique used at each centre, and these details have been tabulated in Table IV.

TABLE IV.—*Details of Biological Tests.*

City.	Biological Tests.	Percentage of Milk Samples Infected.
Glasgow ...	Single guinea-pig inoculation. 1 c.cm. or more sediment inoculated subcutaneously.* Guinea-pig killed at three weeks.	2.6
Aberdeen ...	Si C of milk inoculated. Guinea-pig retained if necessary for eight weeks.	5.5
Edinburgh	half the from the cream layer) inoculated into each guinea-pig subcutaneously. First guinea-pig killed at four weeks; second kept up to eight weeks if necessary.	8.5

*Sediment obtained by allowing milk to settle for twenty-four hours in lon lower layer: quantity of milk varial of milk quoted in these tests refer:

It will be seen from this table that the tests vary at each centre, and that the employment of duplicate guinea-pigs and of a long period between inoculation and post-mortem examination coincides with the highest apparent incidence of infection. It might be assumed from this fact

that the lower incidence of infection of the milk supplies of Aberdeen and Glasgow indicates that, at these centres, the technique is not sufficiently sensitive to demonstrate infection in a number of tuberculous samples. The use of antiformin at Aberdeen, and of a short period between inoculation and post-mortem examination at Glasgow, might account for the variations in the results. On the other hand, there are certain facts which might be urged against such an assumption. At each centre it is usually found possible, by biological test of milk samples, to locate the individual cow which is causing infection of a given milk supply, and this would appear to provide a check on the reliability of the methods employed.* Again, the figure given for the percentage infection of milk from individual cows supplying hospitals (0.56) agrees closely with that obtained from post-mortem examinations of dairy cows at slaughterhouses, where approximately 0.5 per cent. are found to have infected (tuberculous) udders. Further, the discrepancy between the Edinburgh and Glasgow results is so great that the three-week test at the latter centre would have to be assumed to miss more than two-thirds of those samples which would have been found positive by the use of a four- to eight-week test used at the former centre—an assumption whose justification might be doubted.†

If, however, it is assumed that the tests at each centre are strictly comparable, we are faced with a quite extraordinary difference in the incidence of infected milk in the various country districts from which the city supplies are drawn. Such a difference may actually exist, but the criticisms of the tests at the individual centres prevent any definite conclusion being reached.

The outstanding fact brought out in this short discussion is therefore the need for the adoption of a uniform test at each centre. It is only by the standardization of technique that results can be obtained which will be directly comparable and beyond criticism.

The Incidence of Abdominal Tuberculosis.

It is an established fact that a considerable proportion of cases of abdominal tuberculosis is due to infection of bovine origin, and it is assumed that such infection is, in a number of cases, caused by the consumption of tuberculous milk. If tuberculous milk is, in fact, a frequent cause of infection, we should expect that the differences in the incidence of tuberculous milk in each of the three cities referred to above would be reflected in the mortality from abdominal tuberculosis.

An analysis of the number of deaths occurring as a result of abdominal tuberculosis in the cities has revealed the following results.

TABLE V.—*Mortality from Abdominal Tuberculosis.*

City.	Years.	Average No. of Deaths per Million of Population.	City.	Years.	Average No. of Deaths per Million of Population.
Edinburgh	1911-20	120	Edinburgh	1921-27	88
Glasgow ..	1911-18	171	Glasgow ...	1919-27	91
Aberdeen	1913-20	133	Aberdeen	1921-27	92

From these results it appears that while there was a slight variation in the death rate between the cities during the earlier years, the death rates for all four cities during the last eight or nine years have been practically identical, although these were the years during which large variations were found in the incidence of infection of the city milk supplies.

Infection of the population by the consumption of tuberculous milk is obviously more likely to affect the infant population most heavily; it has been estimated that 50 per cent. of the cases of abdominal tuberculosis in children under 5 years of age is of bovine origin, and is to a great extent due to infection of the milk supply. A check was therefore made of the deaths of abdominal tuberculosis in children under the age of 5 years, since this should give a more accurate estimate of milk-borne infection. There was again found to be no considerable difference between the death rates in the two cities, the figures being as follows:

Edinburgh (1921-27)	...	37 deaths per annum per million population.
Glasgow (1921-27) ...	...	31 deaths per annum per million population.

The attempted correlation between the incidence of tuberculous milk and the mortality from abdominal tuberculosis in the cities investigated is, however, complicated by the fact that a considerable portion of the milk supply is pasteurized before delivery to the consumer; and while recent work indicates that pasteurization is not an absolute safeguard against tuberculosis, it very greatly reduces the risk of infection.

If the occurrence of abdominal tuberculosis provides an indication of the relative cleanliness of the milk supply, it appears that the occurrence of living tubercle bacilli in the milk as delivered to the public (that is, after pasteurization or other treatment) is the same for each of the three cities investigated.

The Value of Tuberculin-tested Herds.

The figures which formed the basis of the first section of this paper referred to the incidence of infection in the general milk supply received from country sources. The percentage of infected samples was shown to be variable, but in every case it was significant from the point of view of the possible transmission of bovine tuberculosis to man. In the second section reference was made to the value of pasteurization in decreasing the risk of infection, but it was stated that pasteurization could not be considered an absolute safeguard against tuberculosis.

The movement for the establishment of tuberculin-tested herds was based on the assumption that dairy herds which had been cleared of tuberculosis, and which were subsequently tested at intervals in order to ensure the early elimination of any new reacters, would provide the consumer with a guaranteed tubercle-free milk. The criticism has been made that even these precautions do not give an absolute guarantee of freedom from infection, on the grounds that the interval between periodical tests (usually six months) may permit a cow to develop tuberculosis and possibly therefore to excrete tubercle bacilli in the milk. Such a criticism is *a priori* hardly valid in view of the general recognition that infection of the udder takes place only in the later stages of the disease. Certain results obtained at Glasgow provide, however, a remarkable practical demonstration of the value of tuberculin-tested herds in ensuring the production of tubercle-free milk.

During the years 1909 to 1914 the city hospitals were supplied with milk which was obtained from herds under the strict supervision of the veterinary officer. The herds were not regularly tested with tuberculin, but careful examination of the animals was made periodically and any suspicious animals were at once re-tested with tuberculin. As a result the periodical testing of the milk from these herds *revealed only one infected sample during these five years.*

From 1921 to 1926 the hospitals were supplied with milk from untested herds, and, out of 923 samples examined, 28 (or 3 per cent.) were found to be infected.

During the years 1927 and 1928 the hospitals were supplied with milk from tuberculin-tested herds, and, *out of 550 samples examined, not one sample was found to be infected.* This is the more striking as the quantity of milk tested is relatively large, amounting to approximately half an ounce for every gallon of milk supplied to the hospitals.

These figures effectively demonstrate the entire freedom from infection of milk from tuberculin-tested herds, and illustrate the unique value of such milk from the point of view of public health.

* In this connexion, however, it should be noted that the methods of testing mixed milk (that is, milk from a number of cows) and of milk from an individual cow are not necessarily comparable. In the latter infection is generally heavy, and a short period between inoculation and post-mortem examination may be sufficient to reveal infection; in the former the infection is considerably diluted and a longer period is undoubtedly necessary.

† By the courtesy of Mr. A. Gofton, F.R.C.V.S., I have been provided with the details of the tests carried out at Edinburgh during the last five years. Out of a total of 38 positive samples, 28 (or nearly 75 per cent.) have been diagnosed by post-mortem examination at the end of four weeks. The remaining 10 positive samples required periods averaging about six and a half weeks for diagnosis.

THE RADIUM CLIMACTERIC.

BY

P. CLENNELL FENWICK, C.M.G., M.D.,
F.R.C.S.Ed.,
OFFICER IN CHARGE, RADIUM AND DEEP THERAPY DEPARTMENT, CHRISTCHURCH HOSPITAL, NEW ZEALAND.

In the menorrhagia of middle life radium has proved of so much value that if malignancy and fibroid disease are carefully excluded, radium can be safely recommended.

In this department we have, during the last four and a half years, treated 89 patients suffering from severe uterine haemorrhage. The average age has been 47 years, and the average duration of severe haemorrhage has been two years. Each case has been carefully followed up every three months, and our reports to date show that 73 patients report quite free from symptoms, 2 have been lost sight of, one failed to receive any benefit from the treatment, and 13 have been treated too recently to report. The one failure proved, on operation, to have a large submucous fibroid, which was not detected at the routine examination prior to treatment.

All patients who were sent here for treatment were in a condition of chronic invalidism, often very anaemic, sometimes blanched, and all obviously in a poor state of health. The routine treatment has been one application of radium to the interior of the uterus lasting twenty-four hours: radium element, 50 mg. in platinum tube (wall thickness 1 mm.), enclosed in rubber tube (wall thickness 1 mm.); total dose 1,200 mg. hours. As the uterine applicator is only the diameter of a No. 6 Hegar's dilator, an anaesthetic is seldom required. In no case has any untoward symptom developed. In a few patients transient sickness or headache has occurred; these symptoms cease directly the radium is withdrawn.

In order to ascertain whether the climacteric induced by radium treatment differs in any way from the normal "change of life," I have recently issued a circular questionary to 44 patients who were treated up to 1928. The answers given by the patients are shown in the following tables.

Cessation of Haemorrhage.

Question 1: How soon after the treatment did the bleeding completely cease? elicited the following replies:

	Cases.
At once	20
After one week	1
After three weeks	1
After four weeks	15
After six weeks	1
After eight weeks	4
After six months	1
After seven months	1

With reference to the last two cases I made special inquiries.

The patient who was not symptom-free for six months stated that the bleeding ceased seven days after treatment. She then went a very long tiring railway journey and had a return of bleeding which lasted fourteen days. One month later she had a bleeding, slight in amount, which lasted twenty-four hours. She noticed a pale pink watery discharge, which did not cease till six months after treatment.

The patient who was not symptom-free for seven months was treated in March, 1926. She reported regularly that she was free from any bleeding until November, 1926. She then had a return of bleeding, not severe. I gave a second radium treatment, and she has had no sign of haemorrhage since. This was the only patient who had two treatments.

In a few instances patients have written to say that they have been alarmed because free bleeding occurred after the treatment. In no case has this haemorrhage been as severe as the bleeding present before treatment. In these menorrhagic cases it is impossible to determine when the true menstrual period is present, or due to occur, as the haemorrhage is so irregular and often so prolonged.

If we could choose the time for treatment I think our results would be even better. I warn every patient that one or more bleedings will occur after treatment, but that the haemorrhage will eventually cease entirely.

Frequency of Bleeding.

Question 2 was: How often did bleeding occur after treatment? The replies showed that—

	Cases.
No bleeding occurred after treatment in	20
One bleeding occurred in	17
Two bleedings occurred in	7

Pain.

An investigation as to the presence of pain before and after treatment gave the following information.

	Cases.
Patients who had *no* pain before treatment	24
Patients who had pain before treatment	20
Patients reporting absence of pain after treatment	15
Patients reporting pain still present but less	4
Patients reporting no improvement of pain	1

Disturbance of Micturition.

The number of patients who suffered from painful or frequent micturition, and their condition after treatment, was as follows:

	Cases.
Before treatment	4
Condition improved	3
Not improved	1

Climacteric Symptoms.

The usual climacteric symptoms of hot flushes, headaches, nervous symptoms, stiffness, or indefinite joint pains were investigated.

	Cases.
No complaints were reported in	14
Hot flushes were noted in	29
Headaches in	25
Stiffness or indefinite joint pains	13

(Rheumatism is so prevalent in New Zealand that the complaint of stiffness and vague joint pains is very common among middle-aged people of either sex.)

After very careful inquiry among women who are passing through the normal change of life I can find no evidence that the climacteric induced by radium treatment differs in any way, except in rapidity, from the normal period of disturbance experienced by middle-aged women.

Three younger patients, suffering from tuberculosis of the lungs, were sent for treatment on account of severe and intractable uterine haemorrhage. One patient reports that she does not suffer from severe bleeding any more, but has returned to normal monthly loss. One patient reports that the bleeding has ceased, but she has had two attacks of severe nose-bleeding. One patient reports that haemorrhage has ceased, but chronic leucorrhoea is present.

I have been asked several times to treat young women suffering from severe haemorrhage accompanied by much pain at the monthly periods. I am reluctant to treat young adults, but agreed to give treatment in two cases where the patients' health was being undermined by the severe haemorrhage, and neurasthenia was threatened by the patient's dread of the monthly ordeal. I gave one-third of the routine dose (50 mg. for eight hours), and both patients have reported that the monthly periods are normal and free from excessive pain.

A number of cases of menorrhagia in which a fibroid tumour was present have been sent for treatment. I have always urged these patients to submit to operation, but in six cases I agreed to give treatment because the patient was unable to undergo surgical treatment. In three cases the relief was remarkable, haemorrhage ceasing and other symptoms being relieved. In one case in which a fibroid tumour reaching to within one fingerbreadth of the umbilicus was present, and flooding was present at time of treatment, the haemorrhage ceased within a few days, and when I re-examined the patient six months later I could only detect a small movable uterus and was unable to find the large fibroid tumour I had noted six months before. My last two cases are too recent to report.

I think that with increased experience in the use of radium many cases of intractable uterine haemorrhage will not be allowed to wait until chronic invalidism occurs, but will receive prompt relief from this new ally of our profession.

THE ADRENALINE PACK IN THE TREATMENT OF GLAUCOMA.

Its Value in Temporarily Reducing the Intraocular Pressure.

BY

R. E. WRIGHT, M.D., C.I.E.,

LIEUTENANT-COLONEL I.M.S.,

SUPERINTENDENT, GOVERNMENT OPHTHALMIC HOSPITAL, MADRAS;

AND

K. KOMAN NAYAR, L.R.C.P. AND S., D.O.M.S.,

ASSISTANT SUPERINTENDENT.

In the last decade a large amount of experimental work and clinical investigation has centred round the non-operative treatment of glaucoma. The mass of published material reveals one method which not only has a very practical value, but also raises points of great theoretical interest. We refer to the use of the adrenaline pack. Of the newer non-operative aids to treatment in this condition three stand out prominently: first, the instillation of the "glaucosans" advocated by Hamburger; secondly, the intravenous injection of hypertonic sodium chloride solution (30 per cent.) as described by Duke-Elder; and thirdly, the employment of a pledget of cotton-wool soaked in adrenaline and placed in the superior fornix of the conjunctiva, originally advocated by Gradle, and subsequently reported on favourably by S. R. Gifford and others.

During 1928–29 we pursued a clinical study of over a hundred cases of primary glaucoma from different points of view, but chiefly with the idea of exploring non-operative methods of treatment. The analysis of the series has not yet been published and will take time. Meantime, we consider that it may be of interest to indicate briefly our experience of the three methods referred to, and illustrate by charts some interesting features of the adrenaline pack.

With regard to the first, after a number of observations on the effect of glaucosan drops and amino-glaucosan, we are inclined to agree in the main with the somewhat unfavourable conclusions arrived at by Duke-Elder and Law in their recent article in the *British Medical Journal* of March 30th (p. 590). Of the two, we found that amino-glaucosan, although inconstant in its action, was preferable. It is, however, more troublesome both for the doctor and the patient, and in our hands less frequently of value than the adrenaline pack.

The intravenous injection of hypertonic salines we have only found of service as an emergency measure in acute intractable glaucomas as a preliminary procedure to an emergency iridectomy. However useful, therefore, in a large hospital in occasional cases, it is unsuited for purposes of general utility.

The third method, on the other hand, has proved such a simple and expeditious aid to treatment that we wish to express ourselves in support of those who have favoured its use. We would, however, like to make it perfectly clear that in our experience the best single non-operative method of treatment is the efficient instillation of eserine, that no combination of non-operative methods of which we are aware obviates eventual operative treatment by decompression, and that of such operative procedures we prefer trephining in the majority of cases. It is in chronic primary glaucoma that we have found the adrenaline pack of greatest use. In such cases it may frequently be expected to act as a powerful adjunct to ordinary non-operative treatment. We do not suggest that it gives constant results, but it will sometimes reduce the tension where intensive eserine treatment in combination with other measures fails, and sometimes in a most dramatic manner. It also proves of the greatest value in controlling the tension prior to operation. Usually the first effect of the pack on the glaucomatous eye is to raise the tension. This preliminary rise takes place in the first eight hours; soon a fall sets in, which brings the tension below its original level inside twenty-four hours. The fall tends to continue, and may not reach its maximum till the third day, or possibly later. The preliminary rise may not occur, especially in moderate tensions, or it may be greatly diminished or even prevented by the frequent instillation of eserine, 1/2 per cent., before and after the pack. The fall is temporary, and may in certain cases be small and of short duration. We have known it to fail altogether or to be well marked, but succeeded by a rise in a few hours. Sometimes after several apparently good responses the tension settles down at a higher level than before the treatment was instituted. In moderate cases the fall can be prolonged by the use of eserine. The pack may be used, therefore, to give eserine a start, as it were, and allow it to exert its maximum effect. When the tension starts rising again, in spite of miotics, massage, etc., there appears to be no reason why the pack should not be

repeated. We have effectively repeated this procedure five and six times at short intervals. Up to now we have chiefly used the method in cases where the ordinary non-operative treatment was practically ineffective and in which we desired to get the eye into a more favourable state for operation. It is not our object in this communication to do more than draw attention to the frequently favourable results of the adrenaline pack on the tension in glaucoma of moderate extent. At the same time, we would like to show some effects of considerable theoretical interest in connexion with its use in very high tension cases.

The Method.

The eye is anaesthetized by two or three instillations of 2 per cent. holocaine. The tension is taken with an instrument (we usually use a Bailliart's tonometer) if it is desired to make accurate chart records. If we wish to try and obviate the initial rise of tension due to the adrenaline it is desirable to give eserine frequently before and after the pack—say, six instillations in the hour before, and six half-hourly instillations after. A small flattened pledget of wool is soaked in ordinary adrenaline chloride solution (1 in 1,000, P., D. and Co.), and whilst the patient looks down and the lid is elevated with a retractor, it is laid in the superior fornix and the eye closed. It is left there for five minutes. Should eserine not be used in conjunction with the adrenaline the tension is more likely to rise, but even with marked rises we have not seen an untoward result; there has always been a fall again the following day. In the ordinary case of primary glaucoma the reactions are moderate, and may be slight and hard to demonstrate with the tonometer, although the fall is usually definite. In badly damaged eyes with excessive tensions, however, more startling effects may be obtained, some of which are quite contrary to what might be expected, and more interesting in view of the fact that the vascular tunic in such eyes is markedly atrophic. A few selected charts will better illustrate various responses to the adrenaline pack.

Chart 1.—A case of moderate tension in which there was no rise immediately after the pack on the first occasion and actually a fall on the second. Eserine was freely instilled as described above, before and after the pack. Operation was undertaken before the fall due to the second pack had passed. Eserine alone at first reduced the tension, but it rose on the sixth day.

Chart 2 shows the effect of numerous packs in a case where there was high tension in both eyes. The first pack in the right eye acted well on both, but the second pack, given in the left eye, did not reduce the tension in the right. Thereafter packs were given on both sides. The last packs were not very effective.

Chart 3 shows marked rises immediately after the packs in an eye of moderate tension. The value of the pack in such a case would appear to be doubtful. Small corresponding rises are shown in the untreated eye, which was apparently normal.

Chart 4 shows a marked late fall of tension due to the adrenaline pack without an immediate rise. The tension in the other eye, which did not get adrenaline, shows corresponding variations of tension. The fall due to the pack (in spite of eserine) is not well maintained after the first pack. It is of somewhat longer duration after the second. The patient was eventually treated by operation.

Chart 5 shows the effect of the pack on an eye of very high tension. The rises immediately following the pack are small: the falls are comparatively small and of short duration. A curious feature is the effect on the opposite eye, where the tension behaves in a converse manner to that in the treated eye.

Chart 6 shows the effect of eserine and the adrenaline pack with corresponding falls in the untreated eye. Eventually, after a number of badly sustained falls, a low-level tension of longer duration was obtained.

THE ACETIC ANHYDRIDE TEST OF THE SPINAL FLUID.

BY

G. L. PIOTROWSKI, M.D.GENEVA, M.R.C.S., L.R.C.P.,

PRIVAT-DOCENT AT THE FACULTY OF MEDICINE OF GENEVA.

J. G. Greenfield and E. A. Carmichael have investigated the value of the acetic anhydride test. The reaction was found to be positive in 15 out of 16 cases of dementia paralytica, and a positive reaction might also occur in secondary neurosyphilis; cases of cerebral degeneration were said to give a weak reaction. Greenfield and Carmichael suggested that the reaction might be due to an increased cholesterol content of the spinal fluid.

I have investigated the acetic anhydride test in 88 cases, and give here my first impression on its value. When the investigation could not be undertaken at once we always kept the fluid in the ice-chest, but never waited more than twenty-four hours. One cubic centimetre of fluid is measured in a test tube, and 0.3 c.cm. of acetic anhydride is added; it is then shaken so as to produce an emulsion, and then, drop by drop, 0.8 c.cm. of pure sulphuric acid is introduced. As we often proved, it is of the utmost importance to add the sulphuric acid very slowly; a negative fluid may give a positive result if the sulphuric acid is run in too quickly. In the case of a positive reaction a lilac tint of varying shades appears, but in my opinion is not so fleeting as the authors describe it.

The numeration of the cells of the cerebro-spinal fluid was made with the Nageotte's counting chamber, and the quantity of albumin estimated with the Sicard and Cantaloube process (precipitation by trichloracetic acid); the globulins were detected by the Nonne-Apelt and the Pandy tests. The following are the results in a few diseases.

General Paralysis of the Insane (10 cases).—No relation was found between a positive Wassermann reaction and a positive acetic anhydride reaction, and no association between it and the presence of globulins. In the four negative cases the number of cells per cubic millimetre was always below 3, and the albumin below 0.035 per cent. The acetic anhydride test was strongly positive in two cases, and positive in four patients; in all these cases the cell count was more than 20 cells per cubic millimetre.

Tabes (5 cases).—None of the cases we investigated had more than 5 cells per cubic millimetre in the spinal fluid, and all gave a negative test.

Meningitis (15 cases).—In 6 cases of tuberculous meningitis we had 4 positive reactions and 2 negative; of these last cases one contained 37 cells per cubic millimetre and the other 15 cells, with an albumin content of 0.044 and 0.025 per cent. In three of the positive cases the diagnosis was confirmed by a post-mortem examination. In one case of staphylococcal meningitis of unknown origin (the patient was comatose when admitted to the hospital), with thrombosis of the cavernous sinus, there was a strongly positive acetic anhydride reaction, the spinal fluid being almost pure pus. In two other cases of meningitis there were positive reactions; in one of these an abscess of the temporal lobe was found at the necropsy, but no organism could be found, and the origin remained unknown. In these three cases the albumin was as high as 2.0 per litre, and the cells were innumerable.

Syphilitic Meningitis and Cerebral Lues.—A negative test was obtained in an old-standing case, treated when the cerebro-spinal fluid was normal; in two other cases the test was doubtful. Cytological examination of the spinal fluid revealed 6 and 16 cells per cubic millimetre; 0.025 to 0.035 per cent. of albumin was present, and the Wassermann reaction was positive. In the other cases the test was strongly positive; the meningeal reaction was also positive, there being 80 to 310 cells per cubic millimetre.

Congenital Syphilis.—Two cases, with a negative fluid and a negative test.

Meningeal Haemorrhage (4 cases).—Negative test in all; the spinal fluid contained blood.

Cerebral Degeneration (10 cases).—We could only investigate the anhydride acetic test in 10 cases; the number of cells was never above the usual figure, and the quantity of albumin was always normal. In seven patients in whom degeneration was marked there was a positive or a subpositive reaction.

Cerebral Tumours.—The test was always negative; none of our cases had more than 3 cells per cubic millimetre.

Epidemic Encephalitis (5 cases).—The reaction was always negative, although the number of cells was three times above the normal (up to 27).

Zona.—Three cases, always negative results, and slight meningeal reaction.

Poliomyelitis.—Two cases, each reacting slightly positively.

Various Cases.—In 20 other cases there were 9 of meningism (fracture of the skull, headache, neurasthenia, hysteria). In 5 a weakly positive reaction was found, although there was no question of cerebral degeneration or of syphilis. In all these cases the spinal fluid and the results of the clinical examination were completely normal.

If we except the cases with a slight positive reaction we only get a positive test in general paralysis, in meningitis, and in cerebral degeneration. There is a certain relation between the number of cells per cubic millimetre and a positive reaction; the nature of the cells seems to have

no definite significance, fluids with lymphocytes giving a positive reaction as well as fluids with polymorphonuclears.

We estimated the cholesterol content of the spinal fluid in 15 cases, but the quantities found were even smaller in cases with a positive acetic anhydride test. The addition of cholesterol does not transform a negative test into a positive one. We do not think it is possible to find the explanation of the acetic anhydride test in the presence of cholesterol.

Is the acetic anhydride test to be correlated with the presence of cholin? Kinnier Wilson found cholin present in cases with degeneration of the central nervous system. Guggenheim and Loeffler found also an increased quantity of cholin in the spinal fluid of syphilitic patients (cerebro-spinal syphilis, tabes). We are not able to answer that question, since the quantity of spinal fluid at our disposal was never sufficient to allow us to determine the presence of that substance; but Kaufmann, working on large amounts of spinal fluid, has demonstrated that normal and pathological fluids contain traces of a base which is certainly not cholin (betain?).

We think the positive acetic anhydride test depends on the presence of a substance (cerebroside) secreted or due to the cytolysis of the leucocytes or of the nervous tissues. A drop of sterile pus added to a negative spinal fluid gives a positive test (pyosin). An emulsion in normal saline of liver, spleen, and brain gives a strong positive reaction, especially the liver, which is well known to contain a large quantity of lipoids. With glycocoll and lecithin the acetic anhydride test remained negative.

We are still in doubt as to the exact cause of the positive acetic anhydride test, which is due, in our opinion, to a cerebroside of the type of pyosin.

If we except the cases with a strong cytological reaction, we found a positive test in general paralysis and cerebral degeneration, and we suggest that the acetic anhydride test might be used as an argument in the differential diagnosis between cerebral degeneration and haemorrhage into the brain, or at least to detect a disintegration of the central nervous system. The acetic test is only of value in the absence of any meningeal reaction of the spinal fluid.

Memoranda:
MEDICAL, SURGICAL, OBSTETRICAL.

ABDOMINAL TORSION OF THE OMENTUM.

THE following very interesting case of abdominal torsion of the omentum occurred in my general practice early this year.

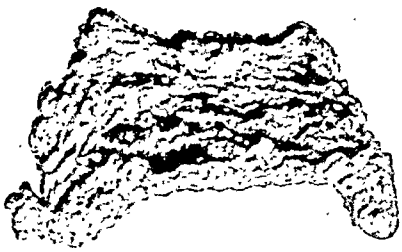
The patient, a man aged 39, was admitted to the Dunfermline and West Fife Hospital on February 22nd with the following history.

For the past six months he had had abdominal symptoms, and three months before his admission *x*-ray examination suggested the diagnosis of duodenal ulcer. A month later he had an attack of pain in the right hypochondrium, accompanied by a rise of temperature; the attack lasted four days. Since then he has had two similar attacks, which were treated by his doctor as acute appendicitis. On February 20th he was seized with severe epigastric pain and vomiting. About six hours after its onset the pain shifted to the right hypochondrium, and remained there till his admission to hospital on February 22nd. Before admission he had been given an enema with good result, but without effect on the pain. On examination, the patient, a fat, flabby man, was seen to be suffering acutely; his tongue was clean and moist, his temperature 101° F., and his pulse rate 108. The abdomen was distended, immobile, and rigid and tender all over; the maximum tenderness was in the right iliac fossa. The percussion note was tympanitic throughout, and the liver dullness was diminished. The signs suggested either ruptured appendix or ruptured duodenal ulcer.

Operation.—The abdomen was opened by a two-inch midline incision above the pubis, and a suction tube was inserted into the abdominal cavity; no fluid was encountered, nor was there any in the pelvis. An incision was then made along the outer side of the right rectus. The caecum was very distended, but the appendix was normal; the transverse colon, too, was greatly distended, but no colonic obstruction could be discovered. The appendix was removed, and the incision then extended upwards. The gall-bladder was normal, but a "doughy" mass, lying high up in the right hypochondrium, was delivered without difficulty. It was of a dark plum colour, and consisted of the great omentum twisted on itself six times. The omentum was removed proximally to the twist, and though the abdomen was further palpated for obstruction of the colon none could be found. The duodenum was palpated, but not seen. On account of the intense distension and thinning of the caecum a No. 12 catheter was inserted into it by Senn's method and brought out through a stab wound in the right iliac fossa.

The patient made an uninterrupted recovery, and was discharged on March 7th.

The removed omentum measured 7 in. by 3 in. Its pedicle consisted of six twists, of which four could be undone easily. The omental veins were greatly distended.



The following are interesting features in this case.

1. A true primary torsion of the omentum appears to have been present; there was no hernia, the appendix was normal, and there were no adhesions.

2. The previous attacks of right-sided abdominal pain with temperature might have been due to an inflammatory state of the omentum preceding the torsion, and a similar explanation might be advanced for the symptoms of duodenal ulcer.

3. The absence of blood-stained fluid in the peritoneal cavity is noteworthy. In the *British Journal of Surgery* of April, 1925 (p. 738), Mr. Ernest Cowell stated that "a rush of blood-stained fluid on opening the abdomen" should remind one of the possibility of omental torsion. The marked distension of the colon, a form of reflex ileus due to irritation of the splanchnic nerves involved in the torsion, has, so far as I know, not been described in other cases.

I am indebted to Mr. Peter Christie of Dunfermline for the photograph.

J. M. BLACK, M.B., Ch.B., F.R.C.S.Ed.,
Honorary Surgeon, Dunfermline and West Fife Hospital.

GRAVITATIONAL MASSAGE.

THE patient, a medical man aged 74, has suffered from severe dyspeptic symptoms continuously for two years, and before that intermittently. Till May this year he had a very poor appetite, and taking food caused considerable pain. He had lost weight markedly, looked sickly, suffered from depression, and had been obliged to give up work. He attributed his condition to previous overfeeding. For some years he had lost the power of vomiting; even when he felt the subjective symptoms of sea-sickness vomiting did not occur. Early in May I became aware that a mass was retained in his sagging stomach. Abdominal massage produced no relief, and it seemed that failure to shift the mass was due to the fact that it was retained by gravitation. Treatment by gravitational massage was therefore tried, and attended by immediate success.

The method adopted was as follows. The patient lay in bed on his back, resting his feet on an article of furniture 3 feet higher than the surface on which he was lying. By flexing his knees and working his head nearer the article of furniture he was able to place his trunk in an almost vertical position, with the result that his stomach changed its position in relation to the pylorus. On performing abdominal massage I at once felt the lump slip down, apparently into the duodenum, and the patient was conscious of immediate relief. Since the regular adoption of this treatment all acute pain has ceased, and the dyspeptic symptoms—as, for example, aversion to food, bad taste in the mouth, mental depression, and sleeplessness—have subsided. The patient's healthy colour, bodily vigour, and normal weight have returned.

Reports of Societies.

PROGRESS IN OBSTETRICS.

AT the seventy-first annual meeting of the Forfarshire Medical Association, which was held at Edzell on June 19th, Professor J. A. KYNOCH delivered his presidential address on recent changes in obstetrics.

Professor *Kynoch* said that the institution of pre-maternity care was the greatest achievement of the obstetric art within the past twenty years. The recognition of midwifery as a branch of preventive medicine was thoroughly justified in view of the immense amount of ill health that could be prevented by ante-natal supervision and the proper conduct of labour. One of the most important single objects of ante-natal examination was the detection of disproportion between the head and the pelvis. The more scientific and reasoned management of malposition of the vertex was one of the most valuable improvements in obstetric practice. Early diagnosis of any existing complication, and the introduction of artificial rotation, had entirely superseded extraction by brute force. Among the unsolved problems of obstetrics none was of greater importance than that of the toxaemias of pregnancy. Within recent years the majority of investigators had pointed to the placenta as the most probable source of the poison; while the lowered incidence of eclampsia during the war years in Continental clinics, as the result of a diet poor in proteids, suggested that the dietetic factor was of the first importance in its development. Nowadays treatment was largely directed to the alimentary canal and to the elimination of toxins, rather than to the obstetrical condition itself. These conservative measures had in great part replaced the more active measures aiming at the rapid termination of pregnancy. Ante-natal care enabled timely treatment to be given, and in this condition has so reduced maternal mortality that if it had done nothing else it would have justified itself. This was one of the many proofs of the urgent need of more ante-natal beds in all maternity hospitals. Information about the haemorrhages of pregnancy had much increased in recent years, but there were still a number of cases that could not be explained on the toxaemic theory; as yet there was no well-balanced explanation to fit them all. The most striking innovation in the treatment of haemorrhages in the later months of pregnancy had been Caesarean section; but many authorities now held that the abolition of shock was of greater urgency than the employment of remedies for the arrest of haemorrhage. The treatment of placenta praevia was also rapidly changing, and Caesarean section to save the child was the latest innovation. Another great advance had been in the treatment of the slightly contracted pelvis; it was now recognized that the high forceps operation must be rigidly avoided. Most gratifying results were obtained by watchful ante-natal care, with timely induction of labour or a justifiable Caesarean section. The induction of labour at or about full time was much more common than it used to be, and the administration of drugs for this purpose had largely replaced operative methods. The practitioner who recognized the need for a timely induction often did a far finer thing than the operating obstetrician who performed a brilliant Caesarean section. Obstetricians could not congratulate themselves on any very marked improvement in the incidence of puerperal fever; the present tendency was for public health authorities to treat puerperal septic cases in fever hospitals, but Professor Kynoch doubted whether this procedure would be helpful in combating puerperal sepsis. He was convinced that the best means to reduce the incidence of puerperal fever was increased and more practical training of midwives and students in a maternity hospital. This, together with closer co-operation between the obstetrician and the laboratory specialist, would enable progress to be made in understanding and solving the cause and cure of puerperal sepsis. The speaker believed that ante-natal care would revolutionize midwifery in the near future; its aim was to ensure the delivery of a living healthy child. But ante-natal care alone was not enough for the mother; the importance of post-natal care was now being recognized, and in that sphere would lie the great advance of the next ten years.

Reviews.

THE ART OF OBSTETRICS.

IT is good to see that there is still a demand for such an old and almost classic work as *Herman's Difficult Labour*,[1] despite the many new, larger, and elaborately illustrated treatises on obstetrics. Those who know the late Dr. Herman's book realize that it is in a class by itself, and that the absolute clarity of its advice, expressed as it always is in crisp and dogmatic sentences, is of very special help in the class of cases which he describes. Mr. CARLTON OLDFIELD, who edited the sixth edition in 1920, has now brought out the seventh edition, and has done the work admirably. A number of additions have naturally been necessary, the most important of which are short chapters on the mitigation of pain in labour, and the prevention of puerperal sepsis. The section on eclampsia has been largely rewritten, and the treatment by the administration of morphine and by lavage of the colon and stomach (what is often known as the Dublin method of treatment) is described in detail. The book is so well known that it seems superfluous to review it beyond this mere statement of the principal additions which have been required in the new edition. These have succeeded in bringing the book up to date in all essential particulars, and it can be most cordially recommended to such practitioners of the present generation as are not already familiar with it, as well as to students, and especially house-surgeons.

The previous editions of Mr. COMYNS BERKELEY'S handbook of elementary obstetrics[2] are so well known to midwives that a description of the volume is unnecessary. The seventh edition has been revised throughout, and room has been found for additional material by omitting the chapters on elementary physiology. The practical instructions in the book are excellent; it is obvious that great care has been taken to make all the details of technique as simple and precise as possible, and the principles upon which these instructions are based are very clearly presented. To the pupil midwife, therefore, this book will continue to appeal, since she will follow easily in its pages the reasons for all the steps which she is taught to take in the care of her patients. The language is everywhere simple, and the author has assumed no more than a very elementary knowledge of physiology on the part of his readers. This has in previous editions made it popular with nurses and pupil midwives, but it is doubtful whether the author's hope that the new and enlarged edition will appeal to obstetric dressers as well as to nurses will be realized. The definition of gonorrhoea as "due to infection by one of the lowest forms of vegetable life, the gonococcus," is not likely to appeal to the average medical student. The book has in the past rightly been the *vade-mecum* of a large number of candidates for the Central Midwives Board examination, and the new edition cannot fail to carry on the work of its predecessors.

INJURIES OF BONES AND JOINTS.

Imperative Traumatic Surgery[3] is the title chosen by Dr. C. R. G. FORRESTER of Chicago for a treatise upon his own methods of dealing with fractures and dislocations and injuries of peripheral nerves. The author describes himself as one who for twenty-six years has confined his attention to traumatic surgery. The title is scarcely a happy one; the ground covered is practically limited to that which the orthopaedic surgeon claims as his own particular province; injuries to soft parts are only referred to incidentally. The many varieties of trauma which may be met with in injuries involving the abdomen are not mentioned at all, so that the rather sweeping title is apt

[1] *Herman's Difficult Labour.* Seventh edition, revised by Carlton Oldfield, M.D.Lond., F.R.C.S.Eng., F.R.C.P.Lond. London: Cassell and Co., Ltd. 1929. (Cr. 8vo, pp xiii + 560, 197 figures, 8 plates. 16s. net.)

[2] *A Handbook of Midwifery, for Midwives, Maternity Nurses, and Obstetric Dressers.* By Comyns Berkeley, M.C., M.D., F.R.C.P., M.R.C.S. Seventh edition. London: Cassell and Co., Ltd. 1929. (Fcap. 8vo, pp. xii + 575; 62 figures, 1 plate. 8s. net.)

[3] *Imperative Traumatic Surgery.* By C. R. G. Forrester, M.D., F.A.C.S. New York: P. B. Hoeber, Inc.; London: W. Heinemann (Medical Books) Ltd. 1929. (6 × 9¼ pp. xxix + 464; 538 figures. 42s. net.)

to be misleading. Apart from this blemish, the book contains much excellent advice on the diagnosis, and particularly the prognosis, of the injuries of bones and joints. The author has evidently made a special study of these from the point of view of their bearing upon workmen's compensation. His attitude generally towards this very important subsection of surgery is marked by a noteworthy sense of fairness to the patient, and in indicating the probable period of incapacity which may ensue after any given injury his estimates are generous rather than erring in the opposite direction.

Dr. Forrester freely acknowledges his debt to Sir Robert Jones, with whom he worked for two years during the world war, and of whose methods he is a whole-hearted admirer. His teaching as regards all the more common forms of fractures and dislocations follow strictly orthodox lines. No startling novel methods are described; the author's plea is for meticulous care and attention to every detail, both in the reduction of deformities and in the after-treatment. Dr. Forrester is not an advocate of very early massage in the case of any injuries in the neighbourhood of joints. His case sheets, of which he gives many illustrations, are an object-lesson in that careful attention to detail which makes so much for success in this branch of surgery, and they bear mute witness to the rather haphazard methods still so general even in most of the teaching centres in this country.

The great value of this book is that it is founded entirely on the very wide personal experience of the author, who only describes the procedures which he has tried out thoroughly for himself. The illustrations are numerous and excellent, the line drawings and diagrams showing the steps of operations being particularly clear.

CLINICAL ENDOCRINOLOGY.

Endocrine Disorders,[4] by Professor HANS CURSCHMANN of Rostock is a compact and agreeable volume intended to present to the physician something on the one hand newer and fuller than what is usually found in formal textbooks of medicine and physiology, and, on the other hand, something shorter, more dogmatic, and more easily digestible than the usual monographs on endocrinology, which are so often full of bewilderingly complicated and contradictory detail. The book is essentially clinical and practical. There are pithy sections on allied subjects, such as infantilism, obesity, and homosexuality, in addition to clear descriptions of the chief glandular disturbances. The chapters on gonadal dysfunctions are particularly valuable, and in these the author has had the co-operation of Dr. FRANZ PRANGE.

Naturally a book of this size does not contain anything startingly new. It is the manner of presentation which constitutes the chief attraction. There are, however, a few deviations from the normal in the volume, such as considerable emphasis on "chronic benign hypothyroidism" and the re-introduction of the term "acromikria" to describe the syndrome of atrophy of the extremities with genital atrophy and diabetes insipidus. Most of the literary and therapeutic references are to mid-European workers, and the author has evidently drawn freely from Falta. Short notes on anatomy, physiology, and histology precede each clinical description, but these are kept down to the minimum. The most interesting chapter is the one on pluriglandular insufficiency. This contains another plea for the recognition of the clinical type originally described by Claude and Gougerot and awkwardly called "pernicious thyro-testiculo-pituitary-subadrenal insufficiency." This syndrome includes cachexia, oedema, loss of hair, debility, impotence, pigmentation, and mental disorder. The prognosis is very bad, except in those cases of syphilitic origin. The syndrome is subject to slight variations, but it must be distinguished from multiple glandular disorders, which are sequential to a disorder in one of the series. It is almost identical with Falta's "primary multiple glandular sclerosis" and Noorden's "genito-sclerodermatic degeneration."

The book is well printed and concisely arranged. The illustrations are numerous and new. There is no trace of the identity of the translator, whose prose is lucid and attractive.

TOXIC SEQUELS OF SPECIFIC THERAPY.

THE increasing use of specific remedies, which are given in doses up to the limit of tolerance, has caused more and more attention to be paid to the undesirable side-actions that occasionally complicate the use of such remedies, and in particular the use of the organic arsenicals. Most writers have been content with the argument *post hoc, propter hoc*, and hence the textbooks contain formidable catalogues of toxic effects which the various drugs are accused of producing. This ever-increasing list of possible dangers adds considerably to the difficulties of specific therapeutics. Critical studies of the toxic effects described have already shown that in some cases, at any rate, the drug is accused wrongly. For example, it is agreed that jaundice following the use of organic arsenicals is in many cases due to the disease, and may be relieved rather than aggravated by the drug. Another striking fact is that a comparison of the toxic effects stated to be produced by specific remedies shows in many cases remarkable resemblance between the effects attributed to drugs of a widely different nature. This curious similarity is explained in a simple and brilliant manner by Dr. G. MILIAN in his book *Le Biotropisme*.[5] His general conception is that the introduction of a specific remedy may exalt the vitality and virulence of organisms existing in a latent form in the patient. He quotes various simple and undoubted actions of this nature—for example, he records cases in which salvarsan administration was followed by the awakening of furunculosis, or by the development of acute malaria without a fresh infection having occurred.

The most important and interesting group which Dr. Milian describes is termed by him "ninth day fever." He shows that the administration of a considerable variety of drugs is followed in certain cases by a similar syndrome. On the ninth day after the first injection there is a mild fever, which lasts a few days and is accompanied by a morbilliform erythema. In other cases the ninth day fever is accompanied by a scarlatiniform rash. The author is careful to emphasize the point that, apart from these ninth day fevers with rash, there are also vesiculo-oedematous eruptions which are direct effects of arsenical poisoning. The ninth day fevers he believes, however, to be due, not to arsenical poisoning, but to the awakening of a latent infection left behind by a previous attack of measles or of scarlet fever. This theory is of considerable practical importance because, if it is correct, then the occurrence of a ninth day fever is not a contraindication to the continuance of the arsenical treatment.

Dr. Milian has collected a large amount of evidence in support of his theory, which undoubtedly goes far to explain many puzzling facts regarding some of the toxic effects observed to follow the use of specific remedies.

ESSENTIALS OF PHYSIOLOGY.

PROFESSOR PONDER'S *Essentials of General Physiology*[6] has been written for the use of American college students who are beginning the study of general physiology equipped with some knowledge of biology, chemistry, and physics. The first 200 pages deal with subjects such as surface tension, colloids, diffusion, electrolytic dissociation, and enzymes, that at first sight pertain more to physics or chemistry than to physiology; the rest of the book may be described as more purely physiological in nature. The author writes clearly, and has not overburdened his text with facts; the illustrations are satisfactory. It may

[4] *Endocrine Disorders*. By Professor Hans Curschmann. With an introduction by Franz Prange. Oxford Medical Publications. London: Milford, Oxford University Press. 1929. (Demy 8vo, pp. viii + 188; 46 figures. 12s. 6d. net.)

[5] *Le Biotropisme*. Par Dr. G. Milian. Paris: J. B. Baillière et Fils. 1929. (6 × 9½, pp. 263; 16 figures).

[6] *Essentials of General Physiology*. By Eric Ponder, M.D., D.Sc. London: Longmans, Green and Co. 1929. (5¼ × 8¼, pp. vii + 497; 150 figures. 15s. net.)

well strike the reader that such a book as this would be best described as an "introduction to general physiology," rather than as an exposition of its "essentials." It may be commended to the attention of those for whom it has been written.

The sixth edition of *Essentials of Physiology*[7] by the late Professors BAINBRIDGE and MENZIES, edited by Professor HARTRIDGE, sets out to supply the medical student with the fundamental facts and principles of physiology in such a way as to enable him to satisfy his examiners in a pass examination. It is accordingly a highly condensed work, and the fact that six editions have been called for since the first edition appeared in 1914 may be taken to prove its excellence. Professor Hartridge has effected a deal of rearrangement of the contents, and has added a number of new chapters and an admirable index. The text is clearly written and full of facts, and the illustrations (nearly 200 in number) are well chosen. But few misprints are to be found, although the words anaerobic and aerobic are misspelt on page 35; a special word of praise may be given to the publishers for the excellent turn-out of the volume. It may be very warmly commended to the attention of medical students revising their physiology.

TREATMENT OF SNAKE BITE.

MR. F. W. FITZSIMONS of Port Elizabeth Museum has spent a lifetime in the study of poisonous snakes, and he has condensed a remarkable amount of information into a small volume of seventy pages, entitled *Snakes and the Treatment of Snake Bite*.[8] He gives a semi-popular description of snakes, snake bites, and snake venoms, and the text is supplemented by a remarkable series of photographs presumably taken in his snake park at Port Elizabeth. The description of the treatment of snake bite is, however, the largest and most important section of the volume. The author says that there is no other book extant on approved methods of treating snake bite, and the need for such a description is best indicated by the fact that the world mortality from snake bite is estimated at about 100,000 per annum. He describes clearly, with full illustrations, the treatment of snake bite by incision, tourniquet, and potassium permanganate, supplemented by serum and saline infusions. One of the most interesting and amusing chapters in this little book is the one which deals with alleged cures for snake bite.

NOTES ON BOOKS.

WE have received a revised edition of the well-known *Introductory Lectures on Psycho-Analysis*.[9] This work is the authorized English translation of a course of twenty-eight lectures delivered by Professor SIGMUND FREUD at the University of Vienna. It does not differ materially from the first edition, which was reviewed in our issue of March 24th, 1923 (p. 516). The subject-matter is divided into three parts: the first deals with the psycho-pathology of everyday life; the second with dreams; and the third with the general theory of the neuroses. These topics were selected by the author as being the most fitted for an introductory course. Written in an easy and attractive conversational style, the book holds the attention of the reader throughout. It will, no doubt, continue to maintain its position as the best general introduction to psycho-analytic theory.

DR. LÉON-KINDBERG'S little book on abscess of the lung[10] gives an excellent account of a pulmonary lesion that seems to be increasing in frequency. A century or so ago Laennec described pulmonary abscesses as very rare, whereas in 1918 Marchand found 72 cases in 222 post-mortem examinations of influenza patients. The author describes the etiology, pathology, symptoms, diagnosis, and treatment of the various forms of abscess found in the lungs, and adds a number of outline diagrams taken from *x*-ray pictures. The book ends with a short bibliography, mainly from French sources, for the years 1926-23; and it may be recommended to the attention of all specialists in diseases of the lungs. It would be improved by the addition of a table of contents and an index.

MR. WARREN R. DAWSON'S little work on *The Custom of Couvade*,[11] or fictitious lying-in of the husband in connexion with childbirth, is divided into six chapters. In the first, which is introductory, the author shows that the custom can be traced back to the time of Theseus, who instituted the ceremony in commemoration of the fatal labour of Ariadne. The succeeding chapters deal with the geographical distribution of the custom in Europe, Asia, the islands of the Indian Ocean, and in America, and the last is devoted to a discussion of its significance. Mr. Dawson shows that the recorded localities in which couvade has been practised correspond in a remarkable degree with those associated with megalithic monuments and with customs connected with the heliolithic culture-complex, of which the other characteristic customs are sun-worship, mummification, ear piercing, tattooing, and cranial deformation. He discusses the various more or less fantastic theories proposed to account for the couvade, and, while admitting that a belief in an intimate relationship between father and child may be the true explanation, comes to the conclusion that we are in the dark as to the original motive of this curious custom. An appendix contains additional material that had become available to the author after the book had been written, and is arranged as addenda to the preceding chapters. A bibliography of 185 references is appended. The work will appeal to all who are interested in anthropology and folk-lore.

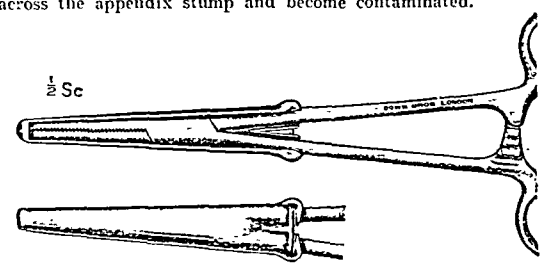
PREPARATIONS AND APPLIANCES.

AN APPENDIX SHIELD.

MR. A. ERNEST SAWDAY, F.R.C.S.Ed. (honorary surgeon, Derbyshire Hospital for Sick Children), writes: The details of technique in the removal of the appendix, particularly the unperforated or "clean" appendix, vary considerably in the hands of different surgeons. The majority of surgeons prefer to insert the purse-string before dividing and removing the appendix, thereby reducing to a minimum the chance of contamination of the peritoneal cavity. Others make a practice of removing the appendix before inserting the purse-string; this makes matters simpler, since the offending organ has not to be held up out of the way, but has the grave disadvantage that it is impossible to be sure that the suture will not fall across the appendix stump and become contaminated.



This danger can be obviated by fitting a shield or sheath over the blades of the Mayo-Ochsner forceps, grasping the stump of the appendix immediately the latter has been removed. Rowlands and Turner state that it is unnecessary to ligature the stump of the appendix, provided it is crushed by a strong forceps for some moments before being covered over by the purse-string.

The steps of the operation would then be as follows: The meso-appendix is ligatured and divided right down to the base of the appendix. The appendix is then grasped at its base by a Mayo-Ochsner forceps, which is closed tightly. A second forceps is placed on the distal side of the first, and as near to it as possible. The two forceps are then laid side by side on a piece of gauze and the appendix divided between them, close to the first forceps. The appendix is removed, the piece of gauze thrown away, and the stump of the appendix lightly touched with a swab, which is thereupon thrown away. The appendix shield is now clipped over the blades of the Mayo-Ochsner forceps on the appendix stump. The purse-string suture is inserted, the shield and forceps removed and laid aside, and the operation concluded in the usual way. If for any reason the base of the appendix is divided before the meso-appendix two shields may be used. The device has been made for me by Messrs. Down Bros., 20 and 23, St. Thomas's Street, London, S.E.1.

THE STATE OF THE PUBLIC HEALTH.

SIR GEORGE NEWMAN'S REPORT FOR 1928.

[FIRST NOTICE.]

THE annual report of the Chief Medical Officer of the Ministry of Health for the year 1928* has now been published. Sir George Newman begins it by defining four basic principles which must be fulfilled before sound foundations can be laid for a national system of preventive medicine. These principles are: the ascertainment and accurate registration of the obtainable data; the establishment of some standards of health and physiology to constitute a base line; an advancing knowledge of the nature of disease, including the social factors which increase or reduce it, and the means of its treatment and prevention; and, fourthly, concerted national activity. He remarks that the medical ideal may not always be socially practicable; proof of its validity is essential if it is to be widely adopted. Its acceptance is dependent upon the assent of the people; its application calls for the expenditure of public money; and the administration must be implemented by the representatives of the people, both centrally and locally. Although the art of medicine cannot control the State, its truths are now available in Statecraft; they have to be accepted and used wisely, since the survival and capacity of a people depend on its health.

Population, Deaths, and Births.

In 1928 the population of England and Wales was 39,482,000, an increase of 182,000 on that of 1927. For more than a generation, owing to the declining death rates, the proportion of children has been decreasing, and that of persons past the prime of life has been increasing. In 1901 11.4 per cent. of the inhabitants of England and Wales were children under the age of 5, and 10.6 per cent. were persons over the age of 55. By 1911 the figure for children fell to 10.7 per cent., while that for persons beyond the prime of life had increased to 11.6 per cent. The war resulted in a fall in respect of the figure for children, the number at the census of 1921 descending to 8.8 per cent., while the figure for those over the age of 55 rose to 13.7 per cent. The Registrar-General's estimate of population in 1928 records a figure of 8.1 per cent. for children under 5, and of 15.8 per cent. for persons over 55, women outnumbering men by more than half a million. Sir George Newman remarks that there is no reasonable doubt that this change in proportion will continue, and that by the middle of the century persons of late middle and old age will be more than twice as numerous as children under 5. The mortality rate will, consequently, become higher, and the picture of a stationary population is almost within sight. The number of deaths of infants under the age of 1 year in 1928 was 42,960, as compared with 45,610 in 1927, 76,552 in 1920, and 94,579 in 1910. These figures indicate the enormous saving of life effected year by year by the reduction of infant mortality. This fall has been most rapid during the first year of life, and there is a lag in the curve for the next few years, implying the need for more attention to be paid to the pre-school child.

Maternity and Child Welfare.

Sir George Newman comments on the increased development during the past year of interest in problems of maternal welfare among all classes of the community. The puerperal mortality rate was 4.42, the highest recorded since the revised classification came into use in 1911. The static position of this rate, it is suggested, may be to some extent more apparent than real; it may be due partly to the diminishing birth rate, with the consequent increase in first pregnancies as compared with later births, and partly to more accurate recording of the cause of death and its association with childbirth. Of the 2,920 maternal deaths, puerperal sepsis is stated as the cause in 1,184 (1.79 per 1,000 births registered). Next in order of frequency come the toxaemic conditions, including albuminuria, uraemia, and nephritis, with 557 deaths; puerperal haemorrhage, with 331 deaths; and other accidents of childbirth with 331 deaths also.

Passing to a consideration of the development of more adequate maternity services and ante-natal clinics, he publishes a memorandum which was prepared by the Maternal Mortality Committee in June, 1929, and deals in detail with the organization and conduct of these clinics. The following figures are given as regards maternity homes and hospitals in England in April, 1929. There were seventy-nine voluntary institutions, with a total of 1,521 beds; municipal institutions numbered seventy-three, with 959 beds; thus there was a total of 152 institutions with 2,480 beds. It is agreed that a shortage of maternity beds exists, both for normal and complicated cases, and particularly for the proper treatment of puerperal sepsis; but Sir George Newman dissents from the view that the solution of maternity problems lies in a vast increase in the maternity beds, mainly in large hospitals, though he would welcome a considerable expansion of maternity accommodation. While remarking that most small grant-aided maternity homes have admirable records and give eminently satisfactory results, he records brief accounts of three outbreaks of puerperal fever to serve as a warning of the risks which are constantly threatening every maternity institution. He draws attention to the point that the nursing or medical attendants of maternity patients may act unwittingly as carriers of infection by harbouring haemolytic streptococci in the nasopharynx, and adds that in certain instances the infection has unquestionably been introduced or spread by this means. He emphasizes the point that, in the event of infection occurring in a maternity institution, it is most important that the throats and noses of all who come into contact with the patients should be examined bacteriologically, and any carriers be isolated and appropriately treated. Sir George Newman hopes that, since under the Local Government Act many hospitals will pass for the first time into the control of public health authorities, this will not only enable additional beds to be provided, but that larger and better equipped maternity units may be formed, which will be either directly or indirectly in association with general hospitals. There will still be a place for small local maternity homes, especially in county areas, though it is desirable that these should be definitely linked up with the larger units. The Chief Medical Officer mentions also the need for better obstetrical teaching for medical students, and, secondly, of encouraging practitioners to equip themselves specially for the practice of midwifery. He refers to two committees appointed by the Minister during 1928. One of these, of which Sir Robert Bolam was chairman, was particularly concerned with the training of midwives and the conditions of their employment; it has now completed its work, and its report may soon be available. The second committee, with Sir George Newman as its chairman, was established to survey the whole field of obstetrical practice from various standpoints, and to make suggestions from time to time based on the findings of special investigations. Three subcommittees—clinical, public health, and research—were formed. The first specific duty undertaken was to advise upon the inquiry which is proceeding into the causation of maternal deaths. It is stated that the response made to the request for information has been very encouraging up to date, despite the considerable amount of time and trouble that has been entailed on all concerned.

Infant welfare centres increased by ninety-one during the year 1928–29. New regulations governing the appointment of health visitors came into force in April, 1928, and some difficulty has been experienced in filling vacancies, particularly in areas where the conditions of service are difficult or unsatisfactory. The number of students has increased, but local authorities are asked to do all they can to encourage more candidates to come forward. An inquiry into the health of pre-school children began in 1924, and nearly 2,000 case sheets await examination.

The Insurance Medical Service.

In 1928 the number of insured persons entitled to medical benefit in England and Wales was 14,814,000, considerably more than one-third of the total population. The

* *On the State of the Public Health.* Annual Report of the Chief Medical Officer of the Ministry of Health for the year 1928. London, H.M. Stationery Office. 3s. net.

number of insurance practitioners in that year was 15,276, and the average number of insured persons on a practitioner's list was 930. There were 9,688 chemists' shops supplying medicines and appliances to insured persons as part of medical benefit, and the number of prescriptions dispensed was 54,455,557. Exclusive of administrative expenses the cost of medical benefit amounted to £9,073,080, of which approximately £6,831,300 was expended in the remuneration of doctors, and £2,241,780 in the provision of medicines and appliances.

From the beginning of 1928 an advisory committee came into force to deal with cases of alleged negligence in the treatment of patients. An officer of the department, who is appointed to hear an appeal in such a case, is associated in the inquiry with a practitioner selected by the Minister from a panel of insurance practitioners nominated by the Insurance Acts Committee of the British Medical Association. In only forty-two out of 299 complaints against practitioners investigated in 1928 by the Medical Service Subcommittee did the Minister decide to withhold remuneration from the practitioner. There were, in addition, eight cases in which remuneration was withheld from practitioners who had failed to keep their medical records, and five cases in which similar action was taken in respect of failure to furnish the regional medical officer with information required. Sir George Newman gives an account of the procedure of investigating insurance prescribing when it is thought to be excessive. The average cost of each prescription fell from 8.4d. in 1927 to 8.31d. in 1928. This follows a long period in which costs due to the frequency of issue of prescriptions, and also those due to the expense per prescription, had risen steadily, though a definite tendency to reduction in the total cost of prescriptions was actually noticed for the first time in 1927. The total expense of the prescriptions issued in 1928 was nearly £20,000 less than it would have been if the cost per prescription had remained as in 1927. Sir George Newman attributes the saving entirely, or almost entirely, to the growing determination of many insurance practitioners to avoid extravagance in prescribing. He thinks that there is reason to believe that this change has been due mainly to the action taken to invoke the co-operation of practitioners, principally by means of interviews which have been arranged with them by regional medical officers in the last four years. It may be recalled that the Insurance Acts Committee was authorized by the conference of local medical and panel committees in October, 1927, to undertake, in consultation with panel committees throughout the country, the compilation of a single formulary which would give due attention to considerations of economy, as well as to other requisite features. Sir George Newman remarks that the results of the labour of the Insurance Acts Committee in this matter are now in the hands of the panel committees, and that if the formulary is adopted by them a considerable saving in the cost of drugs may be anticipated.

Facilities have been provided for some time for practitioners in isolated rural areas to receive post-graduate instruction. In 1928 an attempt was made to extend the field covered by this work, and four additional insurance committees were invited to prepare a scheme. The result, however, was rather disappointing, the total number of practitioners actually receiving instruction being 89, as compared with 100 in the previous year. During 1929 additional efforts are being made to increase the number of practitioners attending the courses. The number of cases referred for examination by the regional medical staff was 372,324 in 1928; this compares with 314,140 in the previous year. In 1926 the number of cases was 380,487, but this large increase was chiefly due to the coal stoppage and cannot be considered, therefore, as a comparable figure.

Operation of the New Local Government Act.

As was only to be expected, Sir George Newman devotes considerable attention to the changes that will occur with the coming into force of the Local Government Act on April 1st, 1930, when the powers and duties of boards of guardians will be transferred to county and county borough councils. He introduces his comments with a historical description to show how the new Act derives its origin from the evolution of local government since the Reform Act of 1832 paved the way to reforming the Poor Law in 1834, and the municipalities in the following year. He points out, in considering the medical issues raised by the new Act, that the remedies provide for defects in the existing structure; they comprise the removal of overlapping as regards the Poor Law and the public health; the more or less complete unification of the public health services, both environmental and personal; and the substitution of a consolidated grant for the old system of multiple grants in aid. After discussing the re-organization and co-ordination of functions, both medical and semi-medical, he puts forward various suggestions how the medical work hitherto carried on by the boards of guardians may be taken over without undue difficulty by the county and county borough councils. The new programme of the medical officer of health is defined, and it is emphasized that the fullest advantage should be taken of the opportunity afforded by the Act for effectively co-ordinating all institutions in the different areas which are concerned with medical or surgical treatment, as well as stimulating active co-operation between public and voluntary authorities and their respective officers. Attention is devoted to the special problems raised by smaller areas. Finally, Sir George Newman recalls the statement in the interim report of the Consultative Committee on Medical and Allied Subjects (1920) that preventive and curative medicine must be closely co-ordinated in any scheme of medical services, being brought also within the sphere of the general practitioner. He concludes: "For the first time in the history of the public health service the medical officer of health has a direct and ample opportunity for closely and effectually co-ordinating in his area all the varied medical services of the State."

(To be concluded.)

INFANT MORTALITY.

THE ENGLISH SECTION OF AN INTERNATIONAL INQUIRY.

AT the instigation of the Health Committee of the League of Nations, it was agreed "that an inquiry should be held into infant mortality in selected districts in the different countries concerned, that this inquiry should be commenced in 1927, should cover a period of twelve months, and should relate to infant deaths which occur during this period, special attention being paid to deaths during the first weeks of life." Subsequently it was decided that for this purpose in each country there should be selected two rural and two urban districts, comparable from the point of view of population and birth rates, one having a high and the other a low infant death rate; and it was afterwards also agreed that stillbirths as well as infant deaths should be included in the investigation. Reports have now been prepared in the countries participating in the inquiry, and the Health Committee of the League of Nations proposes to issue a general report summarizing the findings. Meanwhile, national reports may be made, and that relating to England is now published as by Dame Janet Campbell, with statistical notes by Dr. P. L. McKinlay.[1]

The report relates to the period from March 1st, 1927, to February 29th, 1928, and the areas selected were: urban, Sunderland and Croydon; rural, (parts of) Staffordshire and Oxfordshire; the former in each case having a high infant mortality rate and the latter in each case a low mortality. The primary object of the inquiry was to ascertain as exactly as possible the cause of death of each infant during the prescribed period, and the second object was to state in the light of the results obtained what, if any, steps could be taken to reduce still further the infant mortality rate. The first part of the report gives a general description of the selected districts—not, we fear, a very attractive one—and has more particular regard to their sanitary conditions, their housing, their milk and food supply, and

[1] *Infant Mortality.* By Dame Janet Campbell, D.B.E., M.D., M.S. Reports on Public Health and Medical Subjects, No. 55. London: H.M. Stationery Office. 1929. Price 1s. net.

their public health administration. These particulars will be, in the main, familiar to English readers of the report, and it is satisfactory to note, from the point of view of international reputation, that though the housing conditions are in some instances not what they should be, sanitation, dietary, administration, education, and general intelligence are all good. The second part of the report consists of Dr. McKinlay's statistical analysis of the results of the inquiry, especially relating infant mortality to the order of birth of the infant, to housing conditions, to the economic status of the parents, and to the age of the mother. The third part considers the general causes of stillbirths and infant mortality, and the fourth part gives some general findings and suggestions. There are two appendices: the first consists of the internationally agreed inquiry form and nomenclature, and the second enumerates and briefly summarizes the various English Acts of Parliament affecting the welfare of mothers and young children.

On the whole, it may be said that the general results of the inquiry are interesting but meagre. The findings are confirmatory of previous results of English experience. No new or striking conclusions emerge. Some of these confirmations are quite definite and valuable; but though the report itself admits these facts and the need for caution in any deductions, there yet seems a tendency, though perhaps not a very marked one, to strain after findings and to stretch conclusions to a degree that is not always to be justified without qualification. The statistical chapter is not very easy to follow in all its details unless the reader is an expert statistician. It may be that to such an expert the matter is elementary, but it might easily have been made more possible for him who runs to read. It would have been worth while to have assumed a greater degree of ignorance on the part of the average reader. For instance, it is not everyone who knows, or who can easily discover, what is meant by the values of χ^2 and P; and, although on page 49 a quite clear explanation is given as to the five social classes into which occupations are divided, tabular and other statements with regard to these classes are made ten pages earlier without any explanation. Presumably publications of this kind are intended to be seriously used by a fairly wide circle of interested persons, and some trouble should be taken to treat with due tenderness technical ignorance in respect of some parts of the exposition or the argument. Factors which should make for caution in the findings are the relative smallness of the numbers involved, the absence of adequate controls, the difficulties and possible consequent errors of diagnosis, the impossibility of exact definition of the various social classes, and conceivable fallacies in certain testing criteria. As an example of what is meant by the last of these, we may instance what are called "average housing conditions." From the point of view of health it would not appear to matter whether a group of four or five persons inhabit a house containing ten rooms or one containing twenty—that is, beyond a certain number of rooms per person the existence of an extra number may be regarded as irrelevant for this purpose. But they all appear to be reckoned in the "average number of rooms per person," so that when this average is taken as the standard, and it is said that certain causes of death prevail in houses 25 per cent. above the standard, and certain other causes in houses representing only 89 per cent. of the standard, it is quite likely that the true relative incidence is by no means so disproportionate.

It is recognized that in all countries the four main causes of infantile mortality (including stillbirth) are gastro-intestinal disorders, respiratory diseases, difficulties and injuries during birth, and certain ill-defined conditions such as prematurity, malformation, atrophy, debility, and so forth. It is clear that the first two of these main causes will result in the death of the child subsequent to the first few days of its life, and that the last two causes will operate very largely in causing stillbirth or death within the first day or two after delivery. There are thus two separate problems to be investigated. They are, in the main, quite distinct problems, and there would appear to be no advantage in combining into one whole the facts relevant to each, either for theoretical or for practical purposes. The former problem—that concerned with the mortality of infants more than a few days old, mainly from irritation of the respiratory or the gastro-intestinal mucous membranes—covers a very hopeful field of preventive medicine. The latter problem, as to one part—that concerned with the death of the foetus or newly born infant from causes which are inherent in the stock—can be satisfactorily dealt with only by means of eugenic measures for which mankind is not yet prepared, though as to its remaining part—the treatment of difficult labour—there is a more encouraging prospect. It is perhaps a little unfortunate that the inquiry now under consideration was not, among other things, specifically directed to ascertaining what proportion of stillbirths or neo-natal deaths might properly be attributed to stock defects. This proportion, whatever it may be, will affect very little the mortality rate of the older infants, and it is therefore not surprising that, while between 1900 and 1927 the total infant death rate fell from 154 to 70 per 1,000 births, there has been comparatively little decline in the death rate during the first month of life. The two fields do not offer comparable possibilities, and this should be recognized.

Nevertheless, there is still room for some definite improvement in both fields, and it is well that certain definite facts, conclusions, and suggestions should be emphasized by this report. In the first place, as to nutrition at birth (as evidenced by weight at any rate), differences of ante-natal environment have but little effect. So far as the nutritional state is concerned, the foetus suffers no adverse effect from bad environmental conditions acting on the mother. This is a fact of far-reaching importance, and should be weighed along with the parallel fact, now established, that similar bad environmental conditions do not prevent normal labour being conducted, with due care, as successfully in every respect as in those which are better. Again, as regards birth order, it is found that the risk of death is least in the second and third born infants, that the first born are subject to a somewhat higher mortality, mainly owing to difficult labour and birth injury, but that, with this exception, the risk of death among infants increases in serial order of birth. It seems to follow, and is a fact, that infants born into small families have a much lower mortality than those born into larger families. On the other hand, the age of the mother is apparently a factor of negligible importance in determining the rates of infant mortality, except that the death rate from ante-partum haemorrhage increases steadily with advancing age, and premature birth has the highest rate in young and old mothers. Further, ante-natal and first-day deaths tend to be relatively more frequent in the better social classes and to decline with descent in the social scale. This is true with regard to congenital malformations, difficult labour, and birth injury, and other less definite causes of death; and this fact may be very important in relation to eugenics, though it is unfortunate that the stock defect and the birth injury causes have not been more definitely separated. On the other hand, infant mortality from syphilis and from respiratory conditions is highest among families on the lowest economic level, and declines steadily with improving social status.

Turning now to the actual main causes of stillbirths and neo-natal deaths, they may be placed in four groups. First is the group comprised of those foetuses or infants who, owing either to germinal defect or developmental error, are simply born in a condition which does not allow of existence in the new environment. In the presence of this group we are now helpless, and shall probably remain so with regard to many of them even should revolutionary ideas with regard to the breeding of human stock come to prevail. Next is the group of deaths due to maternal toxaemia, including syphilis. Earlier detection and treatment of this disease in the mother would, of course, lead to reduction in congenital syphilis and in stillbirth or infant death from this cause. A third group is that in which fatality to the infant is caused by placenta praevia, ante-partum haemorrhage from some other cause, and by any other real accident during pregnancy. These deaths, again, it is almost impossible to foresee or to prevent. The fourth group is that associated with some difficulty or delay in labour. It is reasonable to expect that, either by more

careful ante-natal attention or by more skilful delivery, a large proportion of infant deaths in this group might be prevented. The two conditions stressed in the report are prolonged labour and breech presentation. In regard to the former it is said: "It seems probable that the danger of prolonged labour to the foetus is not sufficiently well recognized, and that patients in whom the labour is likely to be unduly lengthy, whether on account of uterine inertia or some other cause, should be sent to hospital more frequently and at an earlier stage than is always done at present." It may be doubted whether hospital is always the remedy indicated. One cause of foetal injury—namely, premature extraction of the head by forceps through imperfectly dilated maternal passages—is certainly becoming less frequent, whether in hospital or in private practice. With regard to breech presentation, it seems likely that the recognition of this condition during pregnancy and the attempt to remedy it by version are not sufficiently common, and that this is true alike at ante-natal clinics and in private practice. The former are certainly, in common experience, not a whit more alert or successful than the latter, though whether everyone will endorse the statement that "external version in competent hands seldom fails" may be doubtful. It is suggested also that "the methods of delivery commonly used for breech presentations are in need of reconsideration," and that a breech delivery should never be regarded as a normal case, and thus within the province of an unaided midwife. It will be remembered that an uncomplicated breech presentation is at present not regarded, under the rules of the Central Midwives Board, as an "emergency" requiring medical aid. We have no doubt that an alteration in the direction indicated would be beneficial.

As has been said, the two important causes of later infant deaths are respiratory diseases and gastro-enteritis. It is somewhat surprising that in the section of the report relating to these conditions no mention is made of smoke abatement as a preventive measure. There are those who consider that the vast improvement in this respect during the present century has been one factor, quite as powerful as the influence of infant welfare centres, which has been very largely responsible for the reduction in the infant mortality rate during that period. In any case, the means of further improvement evidently include those mentioned in the report—namely, more efficient mothering, earlier medical attention, skilled home nursing, and an increase in special hospital accommodation for those infants who are unable to be dealt with at home. The methods indicated for securing these essentials are the better education and training of the mother, the extension of the national health insurance system to the dependants of insured persons, the extension of nursing arrangements now made by local authorities to cover non-epidemic seasons and all types of gastro-intestinal disease, and the setting apart of special hospitals or wards under the recent Local Government Act.

The remarks of Dame Janet Campbell in the last section of the report upon the purpose and management of ante-natal clinics and of infant welfare centres, and upon the need for a national maternity service, are worth careful and serious attention. They indicate the proper place of these things in national public health arrangements. Ante-natal clinics in particular "have a limited function only," and are there "in order to bridge over a difficult period." There are slight indications that Dame Janet Campbell tends to underrate the efficiency of her profession. No doubt there are some members of hospital staffs who are not so expert or skilful as they are supposed to be, and some private practitioners who do not keep themselves as professionally well informed as they should, and who share defects of character with the rest of humanity; but the level of medical education, keenness, and efficiency in the spheres of practice under review is now undoubtedly high. Such statements as that knowledge of infant hygiene and children's diseases "does not penetrate ordinary medical practice with the rapidity or thoroughness which might be desirable: nor is it a question in which the medical student is expected to take great interest"; or as that on page 98 under the heading "Hospital beds," and that on page 104 in the first paragraph under the heading "The confinement," are of doubtful accuracy and value. The summary of suggestions to responsible authorities is wise, useful, and practical, and it may be noted that the "well-organized maternity service available for every woman who cannot afford to provide adequate facilities for herself," which Dame Janet Campbell desires, would be provided by the scheme for such a service approved by the Representative Body of the British Medical Association in July last, and published in the *Journal*, in draft form, in the Supplementary Report of Council (*Supplement*, June 29th, p. 258), and subsequently as a document of the Association.

MALARIAL THERAPY IN GENERAL PARALYSIS.

REPORT BY THE BOARD OF CONTROL.

As was recorded in our issue of August 24th (p. 357), a report by Surgeon Rear-Admiral E. T. Meagher, R.N.(ret.), on general paralysis and its treatment by induced malaria has been issued by the Board of Control.[1] This document is of very considerable practical importance, containing not only a record of the results which have followed the use of this form of treatment in England and Wales, but also an account of malarial therapy as practised in certain Continental clinics.

General Paralysis Historically Considered.

Sir Hubert Bond, a Commissioner of the Board of Control, contributes an interesting historical preface, which comprises a note on the stages by which general paralysis came to be recognized as a clinical entity, the additions made to knowledge about it between 1822 and 1922, and, finally, a brief review of the dramatic change in prognosis since the introduction in the last-named year of Professor Wagner-Jauregg's treatment of the condition by induced malaria. For the depicting of the early part of this period full use is made of the very valuable paper on the discovery of general paralysis, read by Professor G. M. Robertson in 1922, during his year as president of the Royal Medico-Psychological Association, and published in the *Journal of Mental Science* in the following January. The three outstanding figures mentioned in this connexion are those of John Haslam (1798); Esquirol, a pupil of Pinel; and A. L. J. Bayle, the last of whom did so much to identify the disease that, after his death, his name was attached to it in France. Sir Hubert Bond brings out the salient points in the development of knowledge of this disease until 1917–19, when Professor Wagner-Jauregg, head of the psychiatric clinic in the University of Vienna, introduced malarial therapy. Sir Hubert Bond ends his preface with a commendation of the present report. He points out that the prime object of the investigations which led to it was to ascertain in cases of general paralysis treated by induced malaria to what extent, if any, life was prolonged, and what mental or bodily improvement occurred. He deals with some objections and criticisms raised against malarial therapy, and concludes by endorsing a statement in the report that the key to the treatment of general paralysis found by Wagner-Jauregg needs but little fashioning to make it entirely serviceable.

A Review of Cases Treated.

Admiral Meagher begins his survey of the results of cases treated by malarial therapy in county and county borough mental hospitals since this procedure was introduced into England in 1922 by Dr. R. M. Clark and his colleagues at Whittingham. Following this example, eleven mental hospitals recorded the employment of malarial treatment in 1923, twenty-one in 1924, thirty-two in 1925, and thirty-three in 1926 and 1927. As some five years have now elapsed since an appreciable number of the first cases were dealt with, the Commissioners felt that the time had come to review the treatment and its results. Ever since its inception the Board had preserved lists of the patients so treated, and the present inquiry started with an attempt to obtain up-to-date information about their

[1] Board of Control (England and Wales). General Paralysis and its Treatment by Induced Malaria. Report by Surgeon Rear-Admiral E. T. Meagher, R.N.(ret.). London: H.M. Stationery Office. 1929. Price 2s. net.

present physical and mental condition. Admiral Meagher visited many ex-patients who had been discharged from hospitals.

To obtain a standard of comparison the returns of 624 cases of general paralysis (501 males, 123 females) admitted to fifty-five hospitals in 1923, and not subjected to malarial therapy, were used as controls. This particular year was selected because it corresponded with that in which treatment by induced malaria began in some of the hospitals. The results were as follows: 240 (60 per cent.) had died, 52 (8 per cent.) were still in hospital, and 12 (2 per cent.) had been discharged. Examination of these discharged cases indicated that remissions of more than transient duration were decidedly rare; complete recovery was not noted in a single instance. Similarly, of 549 cases admitted to mental hospitals in 1921, 456 (83 per cent.) were dead at the end of 1927, 65 were still in hospital, and 23 had been discharged and were still alive. Combining these results the percentages for general paralysis patients untreated by malarial therapy are as follows: deaths, 86.6; now in hospital, 10.0; discharged, 3.4. Temporary improvement (remissions) occurred in perhaps 2 or 3 per cent., but there was no case of complete recovery.

Sharply contrasting with these figures are those furnished by the patients who were treated by malarial therapy in 1922 and the following years. Eight were so dealt with at Whittingham in 1922; three of these patients are still in hospital and show no mental or physical change; three have died; but two, who have been discharged, are described as being well now and in full employment. Combining these figures with those for 1923 the results are: total cases treated 152; now dead 71; now in hospital 45; now discharged 36. Thus the percentage of those still alive is 53, as compared with 10 per cent. of those untreated with malaria; of the 45 cases in hospital (30 per cent.) it is stated that 14 patients show mental improvement, and in 7 of these there is a physical gain also; in 13 there is no change in the mental state, though 5 have improved physically; and in 18 cases, in 2 of whom there was physical improvement, mental degeneration has occurred. Of the 36 patients discharged, 6 could not be traced, having left the country or having moved to some other town in search of work. There were 17 males at work and earning wages; 3 males were capable of work, but were unemployed; 3 females were carrying on housework capably; 2 patients were unfit for full work, but were able to do occasional work; and the remaining 5 patients showed signs of dementia and degenerative changes which are considered to be slowly progressing.

In 1924 the number of hospitals employing this treatment increased to twenty-two. The figures representing the results of patients treated in this year, and whose condition was investigated at the end of 1927, are: total treated 286; now dead 120; now in hospital 94; now discharged 72. Thus 166, or 58 per cent. of the patients, are still living; this contrasts sharply with the 17 per cent. of those untreated by malaria who were admitted to other mental hospitals in 1924. Of the 94 cases treated in hospitals 34 showed mental improvement, and in all save 4 of these physical improvement also; 36 were unchanged mentally, but 16 had improved physically, while 2 had deteriorated; 24 had degenerated mentally, and usually physically also. Of the 72 discharged patients, 54 were classed as "recovered" and 18 as "relieved," but it is pointed out that these terms cannot be applied strictly in view of the fact that there is no recognized standard of classification adopted by all the different hospitals concerned. Definite information was obtained about 67 of these patients, and it was found that 39 were at work as wage earners, 5 others were temporarily unemployed, 10 were engaged in their ordinary household duties, 4 were undertaking part-time work, and 4 others were prevented from working by some physical disability or other cause unconnected with general paralysis. Five patients showed progressive mental and physical degeneration, and their working capacity is therefore not considered.

Summary of Results.

Surgeon Rear-Admiral Meagher gives next a critical study of the results in the 438 patients treated by malarial therapy before the end of 1924. Of these it was found that 43.6 per cent. had died at the time of reviewing, 31.7 per cent. were in hospital, and 24.7 per cent. had been discharged. Thus 56 of the total number of cases reviewed were still alive, and this may be contrasted with the 14 per cent. of untreated cases admitted to hospital in 1923 and 1924.

Two possible fallacies are considered, of which the first was the question of correct diagnosis. It is concluded that, assuming that the diagnosis can be legitimately based on physical and mental signs, together with examination of the cerebro-spinal fluid, there appears to be no disparity as regards diagnosis in the treated group to give it an advantage over the untreated cases on this score. A second possible source of error suggested was that the treated cases were to some extent selected, the more gravely ill patients not receiving malarial therapy. It is admitted that there is undoubtedly some force in this contention, but statistics are cited to show that if the 438 patients untreated by malaria who had lived longest are selected for investigation only 157 would now be alive, whereas actually 247 of the treated cases have survived. It appears, therefore, to be established that the malarial treatment of general paralysis is calculated to extend life.

The discharges figure of 108 (24.7 per cent.) for those treated by malaria contrasts similarly with the 40 (or 3.4 per cent.) for cases not so treated, and there appears to be very good evidence that real and permanent benefit follows this treatment. Undue optimism on the part of those who practise malarial therapy cannot, moreover, be justly alleged, since it is established that fewer of the patients discharged after malarial treatment died, or sought readmission to hospital, within a period sufficiently long to allow a definite opinion to be formed as to the permanence of the improvement. Of these 180 discharged patients, 77 were able to follow their usual occupation; 10 were mentally well, but fit for little or no work; 10 were mentally unfit for employment; and in 11 the present state was not ascertained. Full details are given with regard to these patients.

Result of Five Years of Malarial Therapy.

Similar reviews of cases treated in 1925, 1926, and the first half of 1927 are given at length, and the figures compare closely with those already determined. Summing up the results of five years' malarial treatment, the total number of patients dealt with was 1,597; of these, 541 (33.9 per cent.) were dead, 652 (40.8 per cent.) were in hospital, and 404 (25.3 per cent.) had been discharged. The average age of these patients on admission was 41, the youngest being 13 and the oldest 70. Twelve cases of juvenile general paralysis are included; it appears that these patients only reached hospital when the disease had made considerable progress and their condition had passed beyond repair. Admiral Meagher contends that it should not, therefore, be deduced that malarial therapy is necessarily useless in the juvenile form of the disease, but may be very effective in early cases.

It appears to have been definitely established that malarial treatment increases the length of life, renders existence more natural, and produces improvement in the physical condition and mental state. In several instances complete recovery seemed to have been achieved, and the treatment offers more promise of success than any other form that has been given extended trial. It is admitted, however, that malarial treatment needs reinforcing, and in this connexion tryparsamide is mentioned, either given before, during, or after inoculation. A short note is added on the way in which malaria acts as a therapeutic procedure, the blood circulation being increased and the whole body being subjected to a kind of "spring cleaning." The dramatic improvement which sometimes occurs suggests also that malaria may possibly possess a specific action antagonizing those spirochaetes which by nature, developmental stage, or age have been effective in causing general paralysis.

Malarial Therapy Abroad.

Interesting accounts are given of malarial therapy on the Continent, with special reference, naturally, to the Wagner-Jauregg clinic in Vienna, which was visited for the purpose of preparing this part of the report, the information being obtained directly from Professor Wagner-Jauregg himself. The countries visited were: Austria, France, Germany, Holland, Belgium, and Czechoslovakia, and it is estimated that about 10,000 cases have been treated in England and Wales and these Continental countries; details of modifications in the procedure encountered are given in each instance.

The report ends with a short but useful bibliography. It is a document which should be in the hands of all who are concerned in any way with the treatment of general paralysis.

British Medical Journal.

SATURDAY, SEPTEMBER 7TH, 1929.

VOLUNTARY BOARDERS.

THE present position of the voluntary boarder is a matter of considerable practical importance, not only to the psychiatrist, but also to the general practitioner; it formed the subject of an interesting and instructive discussion in the Section of Neurology and Psychological Medicine at the Annual Meeting at Manchester. The opening paper, which was read by Dr. Henry Yellowlees, is published at page 446, and, together with the summaries of the remarks of subsequent speakers which appeared in our issue of August 17th (p. 303), merits close attention. To those who are only familiar with the present practice it may come as a surprise to learn that the privilege of entering a mental hospital as a voluntary boarder was originally restricted to those who had previously been patients under certificates, and to relatives of patients who wished to board in the hospital. When it was proposed to abolish these restrictions the Lunacy Commissioners raised many objections to any changes being made, the chief two being that any extension of the privilege would diminish the accommodation for certified patients, and that it would encourage evasion of the law because certifiable persons would avoid certification by entering as voluntary boarders. Even at present, according to the general opinion, the law, strictly interpreted, would prevent any certifiable person from becoming a voluntary boarder, or would not permit him to remain one after he had become certifiable. Although in practice the law is more liberally interpreted, nevertheless the legal difficulty exists, and is liable, therefore, to give rise to anxious problems. In Scotland the question whether the voluntary boarder is of sound or of unsound mind does not arise. Only one condition need be fulfilled for becoming a voluntary boarder in Scotland—namely, a written application expressing a desire to submit to treatment.

The discussion made it evident that some psychiatrists are of opinion that it should be made permissible to treat as voluntary boarders a number of patients who can at present only remain in mental hospitals on a certified basis. The kind of case especially considered was that of the voluntary patient who, exhibiting a change in his symptoms, becomes non-volitional or incapable of expressing his willingness or unwillingness to remain under treatment. In Scotland it is legal for such a patient to remain on as a voluntary boarder. Professor George M. Robertson states that there is only one condition that normally puts an end to the status of a voluntary patient, and that is when the patient himself gives notice of his desire to leave. The onus of taking action to terminate the voluntary status is placed on the patient himself, and the procedure has to be initiated by a definite and unmistakable signal. In England the general practice is to insist upon the certification of a voluntary boarder who becomes non-volitional, though Dr. E. Mapother contends that there is nothing in the law to prevent continued treatment as voluntary boarders of either certifiable or non-volitional patients.

Though some psychiatrists may feel that the voluntary boarder principle should be wider in its applications, the existing law as at present interpreted has been highly beneficial to all concerned. The patient himself is happy to know that he is not being detained under a legal order, but being treated at his own desire. The practitioner is relieved of the feeling, which certification is liable to engender, that he is in part responsible for a procedure which may subsequently place his patient at a serious social disadvantage. As matters are at present it is possible for the practitioner, when confronted with a patient who clearly requires treatment in a private or registered mental hospital, to consider, not so much whether his patient can be certified, but rather whether he need be certified. Dr. Yellowlees states that 69 per cent. of the admissions to The Retreat, York, in 1928 were voluntary boarders, and Professor Robertson points out that at the present time 60 per cent. of the private patients entering mental hospitals in Scotland do so as voluntary boarders. It is certain that a considerable proportion of these patients cannot be said to have deprived certifiable cases of accommodation, since many, no doubt, are patients who would themselves have had to be certified if the voluntary principle had not been admitted. Experience has shown that the psychotic patient, exhibiting, it may be, delusions of various kinds, is not necessarily lacking in a sense of illness. A lively social sense, a keen intelligence, and a definite wish to submit to treatment often exist in combination with psychotic manifestations. Finally, voluntary boarders give an atmosphere of freedom in a mental hospital which cannot be obtained in those institutions in which their admission is not permissible. These voluntary patients cannot fail to act as a stimulus to the medical and nursing staff; their presence, indeed, in the hospital must necessarily ensure a high standard of treatment.

Since voluntary admission has grown into such favour and to such proportions as to amount to a revolution in practice with regard to mental diseases, it is clearly desirable that those patients who would obtain treatment in rate-aided institutions should also be able to do so on a voluntary basis. At present the law does not admit of voluntary admissions in England to the rate-aided mental hospitals, except in the case of the City of London Mental Hospital. In Scotland there is no legal barrier to the voluntary admission of poor patients, and several parishes have agreed to allow suitable patients to reside as voluntary boarders in the district mental hospitals. The Commissioners of the General Board of Control for Scotland have taken a very sympathetic attitude to this problem. They pointed out in a report a few years ago that if pauper patients as well as private patients were permitted to enter mental hospitals voluntarily by a rearrangement of the lunacy grant, the certification of patients, which is not necessary for medical purposes, would fall from the present level of about 100 per cent. to 60 per cent., or even less, of the patients admitted to asylums. Certification would then clearly fall into its proper place as a social and legal necessity. It is quite understandable that the Legislature should be reluctant to relax laws intended to protect the persons and estates of those who are unable to care for themselves and their affairs, but fortunately the introduction of the voluntary boarder principle has enabled progressive movements to develop, whereby experience has been gained of the extent to which relaxation of the law can safely be permitted. The experience gained at the Maudsley Hospital has been particularly valuable, for there it has been found possible to treat on a

voluntary basis mentally disordered patients of all types. The present time would seem to be peculiarly opportune for increasing the number of clinics similar in aim and type to the Maudsley Hospital. In taking over the Poor Law infirmaries and reorganizing the municipal health service, it is much to be hoped that the county councils will bear in mind the pressing needs of those who are threatened with a mental breakdown. In these institutions it is highly desirable to set apart special wards for the treatment of mental cases on modern lines, and any developments in this direction will be watched with interest and appreciation. In the Memorandum of Evidence given on behalf of the British Medical Association before the Royal Commission on Lunacy and Mental Disorder[1] emphasis was laid on the serious need of more flexibility in arrangements for dealing with the mentally unsound. The development of psychiatric clinics in municipal hospitals would do much to solve the problem of the medical practitioner in dealing with the acute and early stages of mental disorder. Briefly, such clinics would afford that "flexibility in arrangements" which is eminently desirable. To apply the voluntary boarder principle to patients entering public mental hospitals would meet a need, but this would not obviate the perhaps still greater necessity for the creation of clinics of the kind suggested above.

THE CONTROL OF ENTERIC FEVER.

HE would be a very hardened pessimist who could study the history of typhoid fever in England without satisfaction. In 1869 the rate of mortality from this disease was 390 per million; in 1929 it is not likely to exceed 9 per million (the rate in 1926 and in 1927). Even since 1911 the rate has fallen to less than one-seventh of that recorded eighteen years ago. A recent Epidemiological Report of the Health Section of the League of Nations[2] presents a valuable comparative survey of the prevalence of, and mortality attributable to, the typhoid group in all countries supplying data. If we scrutinize the table setting out rates of mortality—the least dangerous index for international comparisons—and take the most recent year for which numerous comparisons are possible—namely, 1927—our national self-satisfaction is not in danger of a shock. In 1927 the rate in England and Wales was 9 per million; only three States had better figures—Sweden with a rate of 7 per million, Denmark and New Zealand with rates of 8 per million. In 1926 only Scotland had a lower rate than England and Wales; in 1925 England and Wales had the lowest rate in the table. In the registration area of the United States the rate of mortality is usually five to six times that of England and Wales. In France the rate is about four times ours. The strongest contrast—restricting ourselves to the Great Powers—is with Italy, where in 1925 (the last year recorded and the one with the lowest rate) typhoid fevers were 18.7 times as deadly as in England and Wales. The rate in Italy is, on the whole, a little worse than that of Japan and a little better than that of Spain.

That typhoid fever has been brought under and kept under, so far as the civil population is concerned, mainly by attention to quite simple sanitary precautions, is suggested not only by English history but by the figures of this table. In 1919 the rate of mortality in Germany was higher than in France—63 against 57 per million. In Germany it has continuously and rapidly fallen: in 1927 it was only 11 per million, 17 per million the year before. In France, in 1926, the rate was still 54 per million. It does not need much Continental experience to convince the Englishman that the local sanitary authorities of lands of, broadly speaking, Germanic culture are much more alive to what we conceive to be their duties than those of France. Indeed, the success achieved in this country and in Germany has been the result of steadily (perhaps, some may say, stupidly) practising simple, but very expensive, practical rules. Most of the etiological doctrines of Simon and his contemporaries may have been wrong in detail. In Germany to-day a furious battle is being waged between adherents of the Koch and of the Pettenkofer schools of epidemiology. But the rules of practice deduced from the principle that typhoid is a "filth" disease—that to guard against it one must insist upon clean water supplies in the first place, clean foods of all kinds in the next place, and, finally, that we must cultivate habits of personal cleanliness in the matter of eating and drinking—have been vigorously enforced here and in Germany by "localists" and "contagionists" alike. The result we see.

The League of Nations report contains some valuable statistics of seasonal incidence. It is of interest to note that the summer-autumn maximum is followed in some countries by another maximum in mid-winter. Usually the winter maximum is lower, but not invariably, and the suggestion is made that this phenomenon is worthy of special investigation. The report also contains summaries of the findings in three recent epidemics: that at Lyons in November-December, 1928, the Hertfordshire outbreak in 1927, and the epidemic at Rostoff on the Don in 1926. The first and last of these were traced to water contamination; the Hertfordshire outbreak was probably due to milk contamination. The very unequal sex incidence of typhoid in the Lyons outbreak has been thought to be due to the greater proportion of males recently inoculated against the enteric fevers. The data are very incomplete: although there were 2,430 cases of typhoid, particulars respecting 174 men and 275 women only are available, and no information at all as to the proportions inoculated. The authors are wisely cautious in drawing conclusions, and remark that "it is interesting, however, to note the larger number of women over 50 years of age amongst the cases, as the vaccinated men of this age may be assumed not to have been revaccinated and to be no longer immune." At Rostoff the origin of the epidemic was the breaking of a pipe conducting water from a sterile subterranean spring through grossly contaminated soil. The number of cases was at least 2,935 (1,625 of these in males). Vaccination was offered, but only 12,231 out of a population of 300,000 accepted it. However, 90 per cent. of the army were so treated. The report does not mention the number of soldiers exposed to risk, but says that of the 30 attacked 19 had been vaccinated; of the vaccinated attacked, most fell ill from fifteen to thirty days after the inoculation.

This essay contains much interesting information, and, as we said at the beginning, puts our own country in a favourable light. Quite recent experience, such as that of Bolton-on-Dearne, warns us that we can never afford to relax our precautions, that even now all public water supplies are not free from danger. National history and international comparison prove that our methods are good.

SALT DEPLETION BY SWEATING.

AT the summer meeting of the Institution of Mining Engineers, held at Nottingham, a report—one of a series dealing with atmospheric conditions in hot and deep mines—was received on the salts lost by perspiration caused by high air temperatures. In the absence of Dr. J. S. Haldane the report was presented by one of his collaborators, Mr. W. Hancock, Ph.D., who had spent many hours in the large experimental chamber of the Mining Research Laboratory at the University of Birmingham conducting experiments upon himself. Mr. Hancock stated that acute attacks of cramp were well known to occur among miners and others engaged in hard work in hot places when they drank water freely. Hard muscular work and the drinking of water to quench thirst were the two conditions which appeared to determine such attacks. It was clear that if a man was perspiring freely, and at the same time replacing the lost fluid by drinking water, there would be a tendency for the percentage of chloride in the blood plasma and in the whole body to fall (since much chloride might be lost in the sweat), with a corresponding tendency to a fall in the osmotic pressure of the blood plasma. In the ordinary way this tendency was countered by the action of the kidneys, which excreted excess of water while retaining the chloride; but during hard muscular work the kidneys were thrown almost out of action owing to the diversion of blood supply to the muscles, whereupon the body was left defenceless against the effects of loss of chloride. In addition to this violent and painful cramp, a group of milder symptoms might result, such as depression and fatigue, when the supply of sodium chloride to the body was insufficient to meet the greatly increased loss due to much sweating. The experiments were concerned with the nature of the loss of chloride by the skin under various conditions, and the proportion of sodium to potassium salts. It appeared to the investigators that a sharp distinction must be drawn between two kinds of loss of water from the skin—namely, the evaporation of water which had permeated through the general surface of the skin, and the evaporation or trickling down of sweat secreted by the sweat glands. In the first kind of loss the skin apparently behaved as a semi-permeable membrane—permeable slowly by water, but practically impermeable by inorganic salts, such as the sodium chloride or bicarbonate of the blood plasma. In the second kind of loss—namely, by secretion of sweat—the glands produced a secretion of more or less specific composition, strongly hypotonic in comparison with blood plasma, but removing possibly large amounts of sodium chloride from the body. The first kind of loss depended largely upon the factors which determined the rate of evaporation from the unmoistened skin, and probably also upon the blood supply to the skin; the second kind of loss depended entirely on the activity of the sweat glands. When the rate of loss of water was small the loss was due entirely to the first of these causes, and the small percentage of chloride lost simultaneously seemed to be derived from the epidermis or from sebaceous secretion. The potassium lost in these conditions was far in excess of the sodium which would be needed with it to combine with all the chlorine present. As the loss of water became greater, an increased proportion of the loss was due to true sweating, and the proportion of chloride in the water lost tended to increase, while the proportion of loss of potassium chloride to sodium chloride fell gradually. True sweat, uncontaminated by salts derived from epidermis and sebaceous glands, eventually came to contain about nine times as much sodium chloride as potassium chloride. The percentage of chloride in true sweat, while it increased markedly with the duration of sweating, increased also, though to a much less extent, with abundance in the supply of either sodium or potassium chloride to the body, or as a consequence of reducing the supply of water. The increase in chloride percentage seemed to be due mainly to fatigue of the glands, and for the same reason sweat was produced less and less readily as the sweating continued. The percentage of chloride in sweat, which was always much below that in the blood plasma, was reduced only slightly if water in abundance was drunk or if the supply of chloride to the body was reduced. Therefore, if much water was drunk, with the kidneys out of action as during hard work, acute rise in the diffusion pressure of water might easily be produced, with the characteristic symptoms. Mr. Hancock concluded with the statement that sweat was, roughly speaking, a secretion of more or less specific and markedly hypotonic composition, containing much less chloride than did blood plasma, only about 8 per cent. of the chlorine being united with potassium. No other salts appeared to be present except in traces, although urea had been found in very definitely higher concentration than in the blood plasma. The sweat glands seemed incapable, beyond a very limited extent, of producing sweat which, like urine, varied in composition according as water and other constituents were superabundant in blood plasma or the reverse; their function was to regulate loss of heat from the body or communication of heat to it, and only to a minor degree did they regulate the composition of the blood. As regards prevention of symptoms due to excessive removal of chloride by sweating, all that was needed was a sufficient supply of sodium chloride. By eating red herrings or highly salted bacon, coal miners usually prevented the occurrence of these symptoms, and if stokers in hot climates at sea would add about one-tenth of sea water to the water which they drank during work—just as the coal miner added about 1/4 per cent. to his water or tea—or would eat plenty of salt meat or fish, they could also prevent the symptoms. In some discussion on the report a Birmingham mining engineer stated that during long shifts in the pit at high temperatures, when dealing with pit fires, he had found that abstinence from water produced a curious irritation of the skin, and on drinking copiously he withstood the conditions much better. On the other hand, the president of the Institution, Professor Henry Louis, said that in the tropics he had made it a rule never to drink except at meal times, and when surveying in the jungles of the Malay Peninsula, where the conditions were both hot and moist, he had kept quite well, whereas a companion, who drank freely whenever he felt inclined, collapsed within three days and had to return.

REORGANIZATION OF THE GREEK PUBLIC HEALTH SERVICE.

THE Greek Government appealed last year to the League of Nations for assistance in setting up an improved health service throughout the country, and a deputation subsequently visited certain districts selected by the Greek Under Secretary of State for Health. The situation in Macedonia received special study, and a series of recommendations was eventually presented to the Greek Government, which has accepted them. They provide for the establishment of a unified health service to co-ordinate various public health functions and institutions now scattered through a number of State departments. The existing organization is held to be entirely unsatisfactory, and a new basis has therefore to be devised, so as to protect the service from political influences and to place it under the control of a permanent chief director responsible to the Prime Minister's office. The staff, it is added, should consist of men fully trained in modern methods of hygiene and the prevention of disease, these public health officers being required to give whole-time service and receiving adequate pay. Proposals are made for the setting up of a modern school of hygiene and for training selected Greek medical officers by interchange with those

of other countries, and by individual study tours arranged through the Health Organization of the League. As a first step a training centre is to be established in Athens, with three expert instructors in general hygiene and preventive medicine, malaria prevention, and sanitary engineering. It is stated that the Greek Government proposes to invite experts from other countries to fill these three professorial chairs. The technical services are to be built up, with the help of the training centre, in certain selected areas in Greece, whence the system will be extended later to the rest of the country. The report explains how a permanent Hellenic health service may be built up with the school of hygiene and the new technical services as a foundation, and describes the transitional steps by which it is hoped to have the organization in working order by about 1933. M. Venizelos, in accepting the recommendations, requested the Health Organization of the League to place at the disposal of his Government all its technical facilities, including its technical commissions, in order to ensure complete co-operation in the subsequent development of the plan. The Greek Government has agreed to the increased cost involved, which, when the scheme is in full operation, will amount to about one-third more than the present health budget. Special recommendations are made with regard to hospitals; the prevention of malaria and tuberculosis; labour conditions and social insurance; and a quarantine service. The necessity is emphasized of establishing a special committee to study Greek sanitary legislation, in order to codify the existing laws and render them easier of comprehension and enforcement.

THE VETERINARY CONGRESS.

THE annual congress of the National Veterinary Medical Association of Great Britain and Ireland has been held at Ayr this week under the presidency of Dr. O. Charnock Bradley. Dr. Bradley, who is principal of the Royal (Dick) Veterinary College, Edinburgh, was president of the British Medical Association's Section of Comparative Medicine at the Annual Meeting at Edinburgh in 1927. A considerable number of papers were presented to the congress, of which those dealing with "Foot-and-mouth disease" and with "Mineral requirements of farm animals" were of particular interest to medical men. The first of these papers was read before the Section of Veterinary State Medicine by Mr. J. O. Powley of the Ministry of Agriculture. Foot-and-mouth disease has been present, on and off, in this country since 1839, when the first authentic cases were recognized in Norfolk. In recent years there have been many severe outbreaks, and a considerable amount of scientific information has been accumulated. This has been considered at some length in these columns, and need not be again referred to in detail. Mr. Powley discussed the symptoms as seen in the various domestic animals, and considered the possibility of the natural occurrence of the disease in wild animals. He is inclined to suspect the rat in this respect, although admitting that this is still unproven. The old belief that the virus was easily destroyed has now been abandoned. It has been proved to live indefinitely in the cold in 50 per cent. glycerin, for a month in hay and soil under field conditions—an American case in which it lived for over a year—and for over [illegible] bone marrow. In ordinary hay and [illegible] as long as five months, and when one [illegible] has been transmitted experi- [illegible] one in ten million the [illegible] The modes of entry of [illegible] Ingested, [illegible] inoculated, [illegible] imported [illegible] and rabbits [illegible] by the [illegible]

means whereby outbreaks are caused. Many explanations have been sought to account for the increased number of outbreaks in recent years in Britain: Mr. Powley considers that these are due mainly to the considerable amount of disease in Europe and South America, combined with the greatly increased facilities for trade. The increased knowledge as to the viability of the virus suggests also that many outbreaks, once considered primary and due to outside sources, may well be secondary and due to infections from other localities in Britain. Dr. Orr of the Rowett Institute contributed a paper on the mineral requirements of farm animals. In recent years, he pointed out, the importance of diet and disease had been increasingly recognized, and it was now definitely established that certain diseases were produced, not by the action of a toxic agent, but by the absence of some essential food constituent. Classical diets were concerned mainly with starch values and protein ratios, the actual mineral requirements being largely left to chance. Of these minerals, the most important are calcium and phosphorus. About 2 per cent. of the body weight of a bullock and about 1 per cent. of a pig consists of calcium, while the percentage of phosphorus is only slightly less. A cow producing four gallons of milk a day requires about one ounce of lime and one and one-third ounces of phosphoric acid to do this, while a hen requires an ounce and a quarter of lime for every 200 eggs laid. The problem, however, requires more than a mere knowledge of the weights of minerals necessary for production. Wear and tear have to be compensated for, while the assimilation of the salts in the diet is not complete, and an animal to which has been fed a large amount of minerals may still show symptoms of deficiencies in the tissues. Vitamins and ultra-violet light are two of the factors influencing this assimilation, as also do the nature of the diet, method of preparation, ratios of calcium and phosphorus to each other as well as to the other constituents, and so on. Many of these factors are still little understood. A deficiency of these minerals leads to decreased rate of growth, imperfect formation of bone, nervous symptoms, and generally impaired health in the young; and low production of milk, unthrifty condition, and lower breeding capacity in the adults. Pigs on a calcium-deficient diet develop symptoms closely resembling tetany in children; and in animals, as in man, a diet deficient in calcium results in a reduction of blood calcium. The evidence at present available to support the hypothesis that a deficiency of calcium or phosphorus in the blood leads to a decreased resistance to certain diseases—such as tuberculosis and the pneumonias—is still too meagre to enable very definite conclusions to be drawn; but it is sufficient to stimulate further work and to present a field of investigation of enormous importance in both human and veterinary preventive medicine.

"SNAKE-BITE CURES."

ONE of the most abiding quarrels in the world is that between the rule-of-thumb man who relies on what he believes to be common sense, and the scientific worker who aims at obtaining evidence supported by adequate controls. The latter has been the butt of the wits since Swift described the Isle of Laputa, but it is not always realized how ludicrous may be the results arrived at by the aid of practical common sense when this works, as it usually does, without the embarrassment of any controls. The history of snake-bite cures given by Mr. Fitzsimons in a small book reviewed elsewhere is a case in point. A priori one might expect that it would be a matter of exceptional ease to determine whether a particular remedy does or does not benefit snake bites. The poisonous snakes are well known, the bite leaves a visible lesion; moreover, domestic animals as well as man are frequently bitten, and

therefore it is easy to experiment in methods of treatment. Mr. Fitzsimons gives a list of twenty-one separate "cures," all of which have found wide support amongst the natives or white farmers in South Africa: all of these have been exhaustively tested at the Port Elizabeth Snake Park, and have in every case proved to be of no curative value. Alcohol, in particular, has an established reputation in all five continents as a remedy for snake bite, but Mr. Fitzsimons goes so far as to assert not only that it is useless, but that in many cases it is actively harmful, and he believes that death is often caused by overdosing with alcohol in cases where the patient might otherwise have recovered. Another "cure" was found to consist of ammonia coloured slightly with opium, and yet this proprietary remedy had maintained a reputation in the Cape Province for eighty years. The history of snake-bite cures affords a clear-cut example of the fact that more knowledge can be gained by a few carefully controlled experiments than can be acquired by centuries of practical common-sense clinical experience without the aid of controls. The reason for the absurd results arrived at in this case by the latter method is that the general horror inspired by snake bites has caused their danger to be exaggerated. According to Mr. Fitzsimons, the majority of South African snakes are venomous only in a slight degree, and the really dangerous ones form a minority. Moreover, a bite from one of these highly venomous snakes is not necessarily fatal, for often the snake fails to inject its victim with a lethal dose of venom. Everyone who is bitten by a snake expects a rapid death, but in fact only a proportion of bites are dangerous. Consequently every variety of "snake-bite cure" has, for a time at least, acquired a brilliant reputation.

A SINGLE DIAGNOSTIC CLINIC IN A GENERAL HOSPITAL.

IN the fifteenth annual report, for 1928, of the Peter Bent Brigham Hospital, Boston, Mass., the physician-in-chief, Professor H. A. Christian, speaking with the experience of a chief of a hospital medical service for twenty years, touches on some points in medical education and the organization of the work of the resident staff of the hospital, and then returns to a discussion of a scheme, which he advocated in his report of 1926, for "a single diagnostic clinic," such as is carried on at the Mayo Clinic. With some modification of the existing arrangements it would, he thought, be easy to carry out nearly all the diagnostic work on ambulatory patients before they were admitted to the wards, and that this would be advantageous in saving time and shortening the patients' stay in the hospital. In this scheme there would not be the usual subdivision into medical, surgical, neurological, orthopaedic, and other services, and after diagnosis by this organization the patients would at once receive the indicated treatment by the individual or group especially skilled in that form of therapeutics. The adoption of this plan would in all probability result in the entire abandonment of the division of the hospital into medical and surgical wards, though certain wards might be set aside for special forms of treatment and for post-operative care. In the following year's report his colleague Professor Harvey Cushing, the surgeon-in-chief, commented in a friendly spirit on this proposition to "Mayo-ize" the clinic, and anticipated that, if it were adopted, the hospital would become increasingly surgical, for even at that time the surgeon was called five times as often to the medical wards as the physician was summoned in consultation to the surgical wards. In his reply Professor Christian now points out that physicians, like Jacobaeus of Stockholm and Brauer of Hamburg, who do their own surgery, and his colleague Professor Cushing, who is "a highly developed combination of surgeon, neurologist, ophthalmologist, and pathologist," have greatly contributed to the advance of knowledge, and further that their work emphasizes the artificial nature of separation of the healing art, for indeed they do not recognize any delimiting lines between medicine and surgery. This protest against the conventional distinction in hospitals recalls Sir Clifford Allbutt's address on "The Historical Relations of Medicine and Surgery to the End of the Sixteenth Century," delivered at St. Louis in 1904, in which he insisted that surgery was nothing more than an alternative method of treatment, and that "physic was sterile in proportion to its divorce from surgery." After instancing the example of the gynaecologists, who had rightly assumed control of the female pelvis, he went on "in cerebral surgery, for instance, is it not absurd for one institution to deny, let us say, to Sir William Gowers and Professor Ferrier a liberty which by another institution is granted, let us say, to Professors Horsley and Macewen."

"ULTRA-VIOLET PUBLICITY."

WITH reference to our annotation under this heading in the *British Medical Journal* of August 24th (p. 357), we have received a letter from Dr. A. Eidinow stating that neither Professor Leonard Hill nor he has ever approached the *Evening Standard*, the British Broadcasting Corporation, or any other newspaper, and that they cannot trace the leakage of information. In confirmation of his statement Dr. Eidinow enclosed a copy of a letter from the news editor of the *Evening Standard*, in answer to an inquiry by him, stating that "the information which we published concerning your work in the *Evening Standard* was not obtained from you." We have also received a letter from the Controller of the British Broadcasting Corporation regretting any inconvenience that may have been caused by their announcement on August 14th, and disclaiming any intention of discourtesy. He states that the "news" bulletin broadcast each evening is prepared and supplied by Messrs. Reuters, and that "the particular news item in question was supplied to Reuters, we believe, by the Press Association, and accepted by them in the usual way."

THE KING has re-nominated Sir George Newman to be a member of the General Medical Council for five years from October 9th, 1929.

THE KING has granted Dr. L. N. Robinson, C.B.E., president of the Egyptian Medical Commission in Paris, leave to wear the Insignia of the Third Class of the Order of the Nile, which has been conferred on him by the King of Egypt in recognition of valuable services rendered by him.

LIEUT.-COLONEL C. T. SAMMAN, R.A.M.C., Master of the Society of Apothecaries of London during the past year, was re-elected, on August 20th, Master for the coming year. This is the first time for very many years that a Master has been re-elected.

WE regret to announce the death, on September 1st, of Sir John Campbell, senior surgeon to the Samaritan Hospital for Women, Belfast, and consulting surgeon to the Belfast Maternity Hospital. We hope to publish an obituary notice in an early issue.

Canada.

Dr. Alexander D. Blackader.

A PARAGRAPH in the *British Medical Journal* of August 3rd (p. 215) announced that the Council of the Canadian Medical Association was establishing a Blackader lecture in diseases of children, in appreciation of the services rendered by Dr. Alexander Dougall Blackader, who has lately resigned the editorship of the *Canadian Medical Association Journal*, and as a mark of recognition of his eighty-second birthday. Dr. Blackader graduated M.A., M.D., and C.M. at McGill in 1871, and fifty years later his university conferred on him the honorary degree of LL.D. Part of his early medical studies were pursued in London at St. Thomas's Hospital, and after holding resident posts at Great Ormond Street and the Brompton Hospital he obtained the diploma of M.R.C.S.Eng. in 1876. He was lecturer in paediatrics at McGill University for thirty-eight years, professor of pharmacology and therapeutics for thirty years, and physician to the Montreal General Hospital for twenty-seven years. It is peculiarly fitting that his life-long interest in diseases of childhood should be commemorated by a lecture to be delivered once in every three years by some distinguished paediatrician. The Canadian Medical Association has now paid Dr. Blackader a further compliment by appointing him editor emeritus of its *Journal*, which he conducted for so many years. His successor in the editorship is Dr. A. G. Nicholls.

The Health of Winnipeg.

The holding of the Annual Meeting of the British Medical Association in Winnipeg next year gives a heightened interest to the health conditions of this Canadian city. From Dr. A. J. Douglas's annual report it appears that in 1928 the incidence of typhoid fever was low, eighteen cases occurring with two deaths among a population of 202,377; only ten of the cases originated within the city. A certain number of cases of food poisoning occurred, but they were obviously due to infection with an organism of the salmonella group or a similar organism, and caused no serious after-effects. A considerable proportion of the pike caught in the adjacent lakes are infested with the cysts of *Dibothriocephalus latus*, the pathogenicity of which was established by giving them to dogs and the subsequent recovery of the mature worm; the parasite is, however, easily killed by cooking. Only five cases were admitted into the Winnipeg General Hospital during 1927; the sufferers are usually women, who, it is thought, acquire the parasite by tasting the uncooked spiced fish to ascertain the flavour. The consumption of fruit seems to be free from any danger connected with arsenical spraying. Energetic steps involving considerable expense to the Federal Government and the dairymen are taken to secure the absence of tubercle bacilli from raw milk, which constitutes 40 per cent. of the milk consumed in the city. Under the Municipal Tuberculosis Order the herds of all the dairies licensed to sell raw milk direct to the consumers are submitted to the tuberculin test administered by Federal veterinary inspectors; all reactors are removed from the herd and slaughtered, and compensation paid to the owner. In the report regret is expressed that all the milk supplied to the city is not pasteurized. Small-pox prevailed to a limited extent, but was of the mild type; twenty cases were recorded with no deaths. The outstanding event of the year, however, from the health point of view, was the outbreak of acute anterior poliomyelitis, which started in July and reached its height in August and the first fortnight of September, gradually dying down in October; 225 cases occurred with fifteen deaths; fifteen secondary cases occurred in twelve homes.[1] Satisfactory sanitary conditions were present in a surprisingly high proportion of the homes affected, and a district largely inhabited by people of foreign birth and extraction, living under poor sanitary conditions escaped scot-free. Arrangements were made for early diagnosis and serum treatment: the routine procedure for diagnosis included an examination of the cerebro-spinal fluid; serum was obtained from persons who had had an attack of poliomyelitis; only at first was difficulty experienced in getting enough serum. This service functioned twenty-four hours a day from the middle of August until the end of October.

Considering the health of the city as a whole, the death rate during 1928 was surprisingly low when compared with European rates; the gross death rate was 8.92. During 1927 however, it was even lower, 8.29, the corresponding death rates for London being 12.1; it is possible, however, that some of this difference is accounted for by a larger proportion of older persons in London. The infantile mortality rate in Winnipeg was 63.4 in 1928 and 61.2 in 1927 (in London they were 67 and 59 respectively). The policy of the city is to recommend mothers to engage a doctor rather than a midwife for the confinement; there is no supervision over or regulations governing either trained or untrained midwives in Manitoba, and it is feared that encouragement of midwives might lead to unskilled and untrained women taking up the work. In 1918 19.8 per cent. of the births were attended by midwives; in 1928 only 2.9 per cent. Three-quarters of the births took place in hospitals and maternity homes in 1928. The crude puerperal (maternity) mortality rate in 1928 was 5.1 per 1,000 live births, 0.3 per cent. less than the average for the past five years; for London the corresponding figure in 1928 is 3.09. The outstanding difficulty in the infant welfare work of the city is to persuade expectant mothers to undergo examination, or at any rate to have an early consultation with their doctors.

Winnipeg has its housing and smoke problems. The housing problem is not acute; the population is no longer increasing rapidly—since 1918 the increase has been only 10 per cent. Although no houses are being built to rent, the amount of building (all done by private enterprise) is adequate to provide for the increase of the population; there are even some vacant houses and vacant suites (flats). The chief concern of the health department is the occupation of 3,000 one-family dwellings by several families. Some at least of these families so housed are evidently very poor; they live in one room, and in some cases do not own even the cheap furniture in the room. The health department advocates introduction of sanitary legislation governing such dwellings comparable with the by-laws relating to houses let in lodgings which have so long been in force in London. A start has been made with zoning; a zoning by-law has been passed which is, however, largely permissive, and will require to be supplemented by by-laws creating and setting apart the residential, commercial, and industrial districts contemplated and defined as regards use by the zoning by-law. No change will be required in the use of property the purpose of which is already established at the time of the creation of the zone.

England and Wales.

Care of Mental Defectives.

THE executive committee of the London Association for Mental Welfare, in response to an invitation by the London County Council to put forward suggestions, under the Mental Deficiency Act, 1927, for the extension of the existing provision for training and supervision of defectives, drew up a scheme which is outlined in the association's report for 1928. The committee acted on the principle that the problem might be most hopefully approached by the continued training of those who had already attended an occupation centre up to the age of 16, and suggested, therefore, that two more such centres—making ten in all—could usefully be added and the facilities for "guides" increased. It proposed, further, that classes for needlework, dressmaking, and cookery should be held for elder girls and young women, and that for boys aged 16 to 18 craft centres should be established, where woodwork and simple industries could be taught. Provisional approval of the scheme, and of an immediate suggestion that two classes of the above-mentioned type should be opened in the coming year, was received from the London County Council, and the committee has been invited to submit

financial estimates for carrying them out. In connexion with its work for the London County Council the committee, during the period under review, dealt with 2,564 cases under statutory supervision, a slight increase on last year's figure. It notes with satisfaction that provision for the institutional care of 253 more patients will probably be available during the coming year. Under the committee's care have been 192 patients "on licence" from institutions, 146 of these having been released from the institution for a trial period; so far eleven of this total have been discharged from supervision, and twenty have been recalled to the institutions. There seems, suggests the committee, ground for hope that prolonged training and discipline at institutions does render certain patients of steady character fit to live usefully and profitably in the outside world. This view is borne out by the fact that, at the end of 1928, 77 of the older patients remaining "on licence" were in regular work. A great advance has been in the admission of occupation centre children to many of the benefits of medical inspection and treatment enjoyed by the London County Council elementary and special school children. This change took place in September, since when doctors and nurses have visited all the centres and prescribed treatment. That the children at the centres can now be taken out together and trusted to behave reasonably marks, the committee feels, a definite advance in their development of a community sense. During the year, of 789 children who left special schools, 415 were the subject of inquiry into home circumstances with a view to notification under the Mental Deficiency Acts. The extended power given to local authorities in 1927 to place such children under statutory supervision was exercised in 130 cases. The number of children at school-leaving age who were placed in employment was 802, the highest on record; 156 were placed in skilled, 287 in semi-skilled, and 359 in unskilled occupations. A grant is given by the Board of Control to help the association to carry on activities for the benefit of voluntary cases, and 1,018 in this category were dealt with during the year. This number represents a considerable increase on those of previous years, the association having recently extended the scope of its work to include the care of the mentally unstable patient as well as the definitely defective. Nearly all the 2,751 cases on the association's books during the year have been visited recently, and the information given by the district committees testifies to the value of this method of investigation. Unfortunately the funds of the association do not at present allow of the further retention of the special officer engaged in connexion with these duties, but the committee earnestly hopes that later on it may be in a financial position to undertake them again.

Queen Charlotte's Maternity Hospital.

The increasing strain on the accommodation in Queen Charlotte's Maternity Hospital has rendered extension of the institution urgently necessary, and for some time it was thought that suitable enlargement of the buildings could be provided on the present site. This proved, however, to be impossible, and it was accordingly decided that the hospital should be removed to a new site in Hammersmith. Some account of the proposed transference was given in these columns on February 2nd (p. 220) and on March 30th (p. 627). Work on the new building has now begun, and Princess Mary has consented to lay the foundation stone on November 4th. It is hoped that patients may be received early next year. The hospital when completed will contain 358 beds; it will comprise an isolation block, with thirty beds for the reception of cases of puerperal sepsis; nurseries to accommodate thirty infants; labour wards, pre-natal beds, administration offices, an out-patient department, a students' college, and a nurses' home. In addition there will be a block containing accommodation for eighty paying patients, each of whom will have a separate room at a fee far less than would be charged in a private nursing home. The plans of the new building have been drawn up by Mr. E. Stanley Hall, who has been appointed architect by the committee of management of the hospital. In the annual report of the hospital for 1928, statistical details are given illustrating the urgent need of additional beds. It was thought that the capacity of the hospital had been reached in 1927, when 2,170 patients were admitted, but last year the number rose to 2,375, and, even so, many hundreds of applicants had to be rejected owing to lack of accommodation. The married women patients numbered 1,952, and single women with their first child 423. It is remarked in the report that the contrast between the "booked" and "emergency" cases is most striking, as in previous years. Among the 2,161 booked cases during 1928 there were only four deaths, a rate of 1.8 per thousand; whereas of the 211 patients admitted as emergency cases fifteen died, the corresponding rate being 71 per thousand. These latter patients were almost always sent into the hospital, at very short notice, owing to their being critically ill and often moribund, while the booked cases were patients who had been receiving care and treatment in the ante-natal department of the hospital for many weeks before their confinement. The importance of this ante-natal care is also notable as regards the children, for, while the infantile death rate in emergency cases was 85.3 per thousand births, it was only 14 per thousand in the booked cases. The hospital midwives attended 1,638 patients in their own homes in the districts of Marylebone, Paddington, Kensington, and Kilburn; this compares with a figure of 1,598 in 1927. For the second year in succession there was no maternal death among these patients, and of the 1,634 infants born alive only fifteen died later, a rate of 9.3 per thousand. All the booked in-patients and the district out-patients attend the ante-natal department at the hospital or at the Kensington District Home; the number of patients so supervised last year was 5,804, and their attendances totalled 15,563. These departments are open to patients other than those who are to be admitted to the wards, or to be attended by the hospital staff in their own homes; increasing use is being made of them by medical practitioners and midwives. The number of attendances at the infant consultation centre continues to grow, and last year reached 4,546, as compared with 4,288 in 1927. A special fund is being raised to enable any patient who so desires to have an anaesthetic during her confinement.

Antidiphtheria Immunization in Holborn.

In the annual report of the medical officer of health for the metropolitan borough of Holborn for the year 1928, a strong plea is voiced for the wider employment of the Schick test and immunization against diphtheria, based on the successful work which has been carried on in this borough since 1922. Routine inquiries are invariably made as to the effect of the testing and inoculation on each individual, and it is reported that no disturbance caused was other than negligible. Toxoid antitoxin was employed in order to avoid the risk of improperly made toxin antitoxin. Tables are given showing the results of the Schick tests during the seven years, and also the effects of diphtheria immunization. Dr. Hutt remarks that, owing to the increased confidence of the public in this procedure, it is no longer found necessary to test children under the age of 5, and immunization is at once performed. Of 619 children who were retested seventy were found to be still Schick positive after three inoculations with toxoid antitoxin, and eleven after flocculated toxin antitoxin; the latter has been discontinued for the time being. Up to the end of 1928 only eight cases of diphtheria had occurred in children who had been found positive to the Schick test, and had been treated with three immunizing injections. Dr. Hutt insists that an attempt should be made to immunize all infants as soon as possible after they reach the age of six months; half the number of deaths from diphtheria occur before school age. He adds that in this country immunization on these lines has proved its worth as a means of preventing diphtheria in hospital nurses, and in stamping out the infection in institutions where the disease has been present for a considerable time and has given rise to case after case. Dr. Hutt also calls attention to the danger resulting in the uncontrolled sale of chlorodyne, several preparations of which are on the market and are easily obtainable. He remarks that, since morphine in this form can be bought easily and taken in sufficiently large doses by the general public so as to endanger life, drastic regulations should be made for its use.

Scotland.

Quarterly Vital Statistics of Scotland.

DURING the second quarter of the year 1929 the Scottish birth rate was 20 per thousand; this compares with a rate of 17.2 in England and Wales during the same period. The death rate was 13 per thousand, which is 8.9 less than that of the previous quarter, during which there was a considerable epidemic of influenza; the corresponding rate in England and Wales was 12.1 per thousand. Deaths from violent causes included 145 attributed to accidents with motor vehicles, which number is 16 more than in the previous quarter and 27 more than in the second quarter of last year. The infantile mortality rate was 76 per thousand births, as against 128 in the first quarter of the year; in England and Wales the infantile mortality rate was 62 for the quarter ending June 30th.

New Home for Cripple Children in Edinburgh.

Challenger Lodge, a fine old mansion house, overlooking the Firth of Forth, at Boswall Road, Granton, has been acquired by the Edinburgh Cripple and Invalid Children's Aid Society, the cost of purchase having been covered by an anonymous gift. The house, which was formerly the residence of the late Sir John Murray, the eminent geographer and naturalist, of the *Challenger* expedition fame, and which has served recently as a home for some fifty children of ex-service men under the United Services Fund, is beautifully situated in spacious grounds, and is well adapted for the purpose to which it is to be put. Entry to it will mark a notable expansion of ameliorative endeavour on the part of the society, which for over a quarter of a century has worked unobtrusively and efficiently to advance the claims of the cripple child in Edinburgh and district. The management of the residential home is only one of its activities; another is to supervise and to find employment for cripples who have spent some time in the home, and have left to try to make their own way in the world.

Montrose Royal Asylum.

In his report for the year ending May 14th Dr. C. J. Shaw, superintendent of the Royal Asylum of Montrose, states that the number of patients on the register at the end of the statistical year was 745, exclusive of 44 voluntary boarders; of the total, 240 were private patients. There were 162 admissions during the year; 95 patients were discharged, and 88 died. Twenty-nine were readmissions; two of these had been absent for over twenty-five years. Dr. Shaw regrets that no definite provision has been made in the Local Government (Scotland) Act for the admission of voluntary pauper patients, but hopes that all the new authorities set up under the Act will follow the enlightened policy of many of their predecessors, so that the practice becomes general. Recent additions and alterations included the erection of a new laundry, replacement of the old method of heating the hospital by a modern hot-water circulation, renewal of the cooking appliances, installation of a high-speed electric generator, and the construction of a new reservoir. Under the scheme instituted by the Carnegie United Kingdom Trust, a branch of the county library had been installed in the hospital; a large and varied assortment of books was provided and regularly renewed. A profit of over £900 had been made on the farm and garden during the year.

Control of Dangerous Mental Defectives.

In the course of a speech thanking the corporation of Glasgow for the hospitality shown to Lord Mackay and himself during the recent sitting of the High Court of Justiciary in the city, the Lord Justice Clerk (Lord Alness) raised the question of whether the existing machinery was adequate in preventing dangerous mental defectives being at large in the community. His lordship remarked that he was led to raise the point by the impression left on his mind by one of the two murder charges tried before the court on that occasion. The accused, who was found to be of unsound mind and unfit to plead, had apparently been going about the world in that mental state since his discharge from an institution some considerable time previously, with the result that he shot a young woman dead and attempted also to shoot a man. The case, to his lordship's mind, disclosed a rather disquieting state of affairs, and he suggested that the whole matter of the control and segregation of mental defectives required further investigation and consideration by the appropriate authorities, with a view to seeing whether some machinery could not be devised which might tend to prevent the recurrence of such deplorable accidents.

Ireland.

Proposed Village Settlement for Dublin.

A PROPOSAL is under consideration for the establishment of a village settlement in connexion with Peamount Sanatorium, Dublin, and, consequently, a large audience listened with keen interest recently to a lantern lecture in this sanatorium by Dr. P. C. Varrier-Jones, who is director of the Papworth Village Settlement in England. Sir Conway Dwyer, M.D., presided. Dr. Varrier-Jones said that his objective was the lifting up in the social scale of those suffering from tuberculosis, and who were slipping downwards. When he was a tuberculosis officer he saw many men and women stricken down with the disease; he used to examine them and send them to sanatoriums. They came back after three or six months very much better; their coughs had disappeared, and they had gained weight. But then the question arose about their occupation. A few had sympathetic employers, who were willing to take them back and give them an opportunity of going on with their work. The light, open-air job was a myth, and every medical practitioner who recommended such employment for a consumptive knew that it was useless for him unless he was content with light wages at the end of the week. They had to decide what they could do with the great number of people of that kind, and the suggestion he had to make would not, perhaps, be a national remedy. But, as regards the individual, they had to find a solution that would raise him up and make him a healthy, self-supporting citizen. Tuberculosis was essentially an economic problem. The man who had a good balance in the bank, and could go to Africa or South America, or elsewhere, was not faced with the severe economic difficulty which faced the working man when he returned from an institution. Could they make it possible for the ordinary individual to have a little bank balance after his treatment? The answer was that it could be done if that man was enabled to earn his living in sheltered institutions. The pace at which people had to work at present in industry was too great. It was an age of machinery, and men had to work to keep pace with machinery. It was necessary to reduce that pace, so that the damaged lung could function in the damaged body. When they put a man in a position to earn his money without injury to the damaged organ they were lifting him up. The man was faced with two enormous adverse factors at present—namely, the employer and the fellow worker. A consumptive could earn his own wage, but he could not earn enough to cover the overhead charges which were necessary to keep the whole business going. If an environment could be created so that the overhead charges could be paid by somebody else the consumptive could earn his own living, have his own house, and be a free man. If his family grew up free from disease, then the vicious circle had been cut as it never had been cut before. Village settlements had been started in Germany, Holland, France, and New South Wales, and they were coming into existence in the United States. Dr. Varrier-Jones expressed the hope that Ireland would take up the project with enthusiasm. He then showed a large number of lantern slides of the Papworth Village Settlement, illustrating the houses for the residents, carpenters' shops, cabinet-making factories, handbag factories, and printing shops. He added that men

and women were being employed there under ideal conditions, and the products of their labour were sold to firms in London and elsewhere. Trade union wages were paid, and the inhabitants of this model village lived healthy, prosperous, and happy lives. Sir Conway Dwyer conveyed the thanks of the audience to the lecturer. It is announced that a committee has been formed to perpetuate the memory of Sir William Thompson, M.D., and that the memorial would take the form of a settlement in connexion with the Peamount Sanatorium.

Wexford County Health Board.

At a recent meeting of the Wexford County Health Board a letter was read from Dr. E. Connolly on behalf of the Wexford Poor Law medical officers. Dr. Connolly stated that he had been instructed to inform the board that the doctors were determined not to accept a fee less than £6 6s. for temporary duty. With regard to substitutes, he added, a doctor going on leave was bound by the regulations to nominate his substitute; it was not clear, therefore, how the employment of a doctor other than his nominee entered into the case. After discussion the board decided to fix the weekly remuneration at five guineas. A letter was also read from the Department of Local Government and Public Health stating that the board had decided not to provide accommodation for married cases of maternity at the County Hospital, and with reference thereto it was the Minister's view that accommodation at the hospital for this class was absolutely necessary and should be provided. The Department pointed out that the former operating theatre in the old workhouse infirmary would make an ideal ward for the purpose, and that there were also wards on either side of it which could, with very little expenditure, be rendered quite suitable for accommodating the patients. In these circumstances the board was requested to provide the accommodation in question, but after discussion it was decided to postpone the question for twelve months.

Correspondence.

THE PROBLEM OF THE UNFIT.

SIR,—Your reference to this subject on August 17th (p. 318) comes very opportunely. Without entering into any detailed comment on the article by Dr. K. B. Aikman to which it refers, I think there is no doubt as to the accuracy of his main thesis: and this, with the consequences which inevitably follow, cannot be too widely known.

The essential fact is that for the past two generations the nation has been breeding relatively more and more from its dregs and less from its cream. In other words, the steady fall in the birth rate which has taken place during this time has not involved all sections of society to the same extent. It has been, relatively, considerably greater among the more intellectual, capable, and socially efficient members of the community than it has among the intellectual dullards, the least capable, and the social inefficients. It needed little prevision on the part of those who were aware of this fact for them to realize that it could only have one *result—namely*, a gradual deterioration of the nation's fitness and efficiency. As a matter of fact, the danger of this has been pointed out in previous years by many persons, and I have myself drawn attention to it on numerous occasions during the past twenty-five years. But the process of deterioration has been so gradual as to be practically imperceptible during the lifetime of any individual, and this, together with the lack of any sufficient statistical evidence, has caused these warnings to pass unheeded and to be merely voices crying in the wilderness.

During the past few years, however, evidence has gradually accumulated showing that what was foretold is actually happening. Thus, statistics derived from the medical inspection of school children show that at least one-sixth of the children of school age are so physically or mentally defective or diseased as to be unable to derive reasonable benefit from the ordinary form of education which the State provides. Further, that there are no fewer than 600,000 backward children in the country, and that these add 50,000 recruits to our industrial army every year who are not only unprepared, by mental retardation, to meet effectually the demands of full life, but who furnish society with the bulk of its inefficient adults—criminals, paupers, mendicants, and unemployables. National health insurance statistics show that in one year—that is, 1923—the amount of sickness in England and Wales was equivalent to the total loss of 20½ million weeks' work. This was sufficiently serious; but in the year 1927 the amount of this sickness equalled a loss of over 26½ million weeks' work. The examination of approximately 2½ million men of military age during the year 1918, who were considered to be a fair sample of the manhood of the country, showed that only one-third could be regarded as perfectly fit and healthy. Lastly, the recent investigations made by Dr. Lewis for the Joint Mental Deficiency Committee show that, whereas in 1906 the number of mental defectives as ascertained by the Royal Commission was 4.6 per 1,000 population, corresponding to a total of 150,000 in England and Wales, in 1926 they amounted to at least 8 per 1,000, equivalent to a total of 314,000. No doubt some of this increase is due to a more complete ascertainment, but it is impossible to resist the conclusion that the proportion of mental defectives to the general population is greater than it was a generation ago.

In view of these figures, derived from such widely different sources, but all pointing to the same conclusion, it is not unreasonable—indeed, it is surely of vital importance—to ask how it comes about that after fifty years of modern preventive medicine, after the expenditure of many million pounds upon health services, and after the undoubted improvements which have been effected in feeding, housing, conditions of work, and environment generally, all the indications point to a deterioration rather than to an improvement in the mental and physical health of the nation. The answer seems to me to be plain. These qualities are the resultant of two factors—namely, inheritance and environment. In the past our efforts have been directed solely towards the latter, and we have paid absolutely no attention to the question of inborn qualities, *in spite of the fact that these are probably of far more* importance. In other words, notwithstanding our alleged advances in scientific outlook and method, we have been, and still are, quite content to treat symptoms as they arise, and to ignore the disease of which they are merely the manifestation. Personally, I am convinced that so long as we are satisfied to adopt this partial and illogical attitude, so-called "preventive" medicine will do no more than continue to lop off a few dead and dying branches from the tree of life. It will certainly fail to improve the vigour of that tree, and to prevent its deterioration. There is, therefore, at the present day urgent need for an inquiry into the inborn factors which are responsible for ill health and inefficiency, together with the means by which their origin and transmission may be prevented.

It is clear, however, that an investigation of such a complex matter will be far more likely to be successful if it is restricted to some definite and important disease. Such a condition exists in disease of mind. It is now recognized that mental disease, and particularly mental defect, is not only in itself of extreme social importance, but that it stands in very close relation to many other forms of physical and social inefficiency. It may, indeed, be said to constitute an indicator of such inefficiency. For these reasons it is a pre-eminently suitable subject for such an inquiry, and I have no doubt that a full investigation of the causes of, and methods of preventing, mental disease and defect would not only throw important light upon this particular subject, but would also add greatly to our knowledge of the genesis and prevention of disease in general. Since it is to our profession that the health of the nation, both present and future, is entrusted, and the country rightly looks to it for guidance on such matters, it seems to me to be plainly our duty to draw public attention to this question, and to urge upon the Government the need for such an inquiry. I may add that quite recently the Central Association for Mental Welfare and the Royal Medico-Psychological Association have forwarded to the

Government resolutions pressing for such an investigation. But the matter is too large and too serious to be left to special societies; it is one which should receive the support of the whole medical profession.—I am, etc.,

London, W.1, Aug 26th. A. F. TREDGOLD.

ANTE-NATAL CLINICS.

SIR,—The leading article on this subject on August 17th (p. 315) will attract widespread attention. The warning given to the profession that it may lose control of obstetrics is timely, as the ultimate possibilities of these centres have not been fully appreciated by the doctors in whose districts they have been established. Properly run, ante-natal centres have more than a propaganda value, certainly in industrial areas. In a paper published in your columns on April 13th (p. 691) I suggested that in such areas centres should be placed at the disposal of doctors for the examination of their patients, and where the routine supervision (urine testing and so on) would be carried out for them by the nurse in charge. The present method of running centres has three obvious defects.

1. Many centres are mixed up with "*mothercraft*" and child welfare. The clear-cut entity of ante-natal care, as understood in hospital and private practice, is apt to be lost in the confusion.

2. In many instances there is *no justification* for the officer in charge to come into a district and see patients who will be under the care of the local doctors or midwives. These last should send their cases to be seen by the doctors who will be called in by them in cases of emergency. The position is aggravated if the officer in question, as is frequently the case, has little or no obstetric experience. Even a specialist so employed should not be doing the routine work of doctors, but should be acting in a consultative capacity.

3. The public are led to believe that ante-natal care is a discovery, and something about which their own doctors know nothing. They, and the midwives, tend to short-circuit the local doctors, which will be to the ultimate detriment of obstetrics.

Realizing these points, my colleagues Professor Ranken Lyle and Mr. Harvey Evers and I have agreed on a policy which we hope to see in actual operation in two areas in the near future, and which appears to us to be the soundest method to adopt in the development of these clinics.

In the areas in question there will be a centre at which, at monthly intervals, one or other of us will attend for consultative purposes, but at the outset to start the centre. The local doctors have been approached, and those who wish to take part will have their names, with their days and hours of attendance, notified at the centres. Their attendance will be in couples on days during the week following our monthly visit, but later will almost certainly be at weekly intervals.

Routine cases seen by us will be referred to their own doctors on their days of attendance, and midwives' patients will be encouraged to see the doctors who would have been called in if necessary. The doctors in attendance at the centre will be able to send cases on which they wish to have a second opinion to us on our day of attendance. In these areas the local authorities are arranging to provide expert assistance in ante-, intra-, and post-partum problems for those patients who cannot afford a private consultation. There is also to be a close association between the clinic and the Princess Mary Maternity Hospital. Special post-graduate instruction in ante-natal care is being arranged by the medical school authorities for those doctors who wish to have a refresher course.

Such centres will have a propaganda value, but it is a vital part of our policy that the raising of the standard of obstetrics in this country can only be effected by strengthening the position and giving every possible assistance to those members of the profession who have to bear the brunt of this highly responsible and often most arduous work.—I am, etc.,

Newcastle-upon-Tyne, Aug. 26th. E. FARQUHAR MURRAY.

THE NEW VACCINATION ORDER.

SIR,—The Ministry of Health's circular to which attention was called on August 24th (p. 371) was issued with a view to lessening the occurrence of "post-vaccinal nervous disease," and is now in the hands of public vaccinators. The general idea seems to be not to make the vaccination too successful; to propose one linear insertion instead of four scraped surfaces. Timid mothers have often asked me whether one or at most two places would not be enough. To them I reply: "If you use the same amount of lymph in one place only, the reaction at that place will be more than if it is spread over four places. Would you sooner have four pimples or one big boil? Again, one or two places may not take, but out of four probably one or two will take. It may save doing it all over again." This argument usually overcomes the mother's objections. Now the Ministry is adopting the attitude of the timid young mother. It seems to me a halting attitude; if vaccination is desirable it should be made as effective as possible.

Importance is attached to the production of a minimum of trauma. Infants seldom develop enlarged axillary glands, but adolescents do so in a larger proportion, whether primary or revaccination is performed. I have always considered this as due to the impossibility of sterilizing the adult skin without sterilizing the lymph. We know that during a long operation the deeper layers of epidermis working to the surface are found not to be sterile. The enlarged glands seem to denote the circulation of some material, septic in nature, other than the filter-passing bodies in lymph. The circulation of this may activate the meningeal germs which have been lying quiescent, perhaps in adenoid tissue in some part of the body. The amount of trauma induced by cross-hatching seems to me unimportant in the sterile skin of infants.

On the financial side further duties are imposed on the public vaccinator, but nothing is said of increased remuneration. At present the fee I am entitled to for vaccinating at my house is 2s. 6d. for two visits—1s. 3d. a visit for incurring very considerable responsibility. The scandal of public vaccinators not being regarded as servants of the Ministry—and therefore not being pensionable—remains.—I am, etc.,

Bournemouth, Aug. 25th. GEORGE MAHOMED, Public Vaccinator.

SIR,—With reference to the new Vaccination Order, the most successful vaccinations I ever witnessed were performed by a former colleague of mine, the late Arthur Caesar, who was public vaccinator for the Eastern District of Mile End Old Town. With the lower part of the cutting edge of a broad spear-headed lancet, held almost flat to the skin, by a gentle incising movement he slightly lifted the epidermis, forming, as it were, a valve shutting in the lymph. He never scratched with the point, scarcely drew blood, was nearly always successful, and very little inflammation followed the operation.—I am, etc.,

Teddington, Aug. 27th. FREDERICK WILLIAM ALEXANDER, Late Public Vaccinator, Western District, Hamlet of Mile End Old Town; formerly M.O.H., Metropolitan Borough of Poplar.

ACUTE ANTERIOR POLIOMYELITIS.

SIR,—Mr. Whitchurch Howell's letter on the above subject on August 17th (p. 323) is opportune in view of the increased prevalence of acute cases of the disease at this time of the year. Ignorance of the vital necessity of efficient early treatment of the paralysed muscles is, however, so general that I wish Mr. Howell had given more detailed information about the steps to be taken. The services of an orthopaedist are not everywhere available, and the practitioner is apt, moreover, on meeting with an acute case, to turn for advice to medical rather than to orthopaedic writings. In books on orthopaedics the necessity for splintage of the affected parts so as to rest the paralysed muscles from the moment of onset, and the positive danger of massage and electrical treatment in the early stage, are emphasized; but in medical works the

practitioner finds either no mention of local treatment at this stage or vague advice as to massage and "electricity." The general treatment advised—hexamine by the mouth and convalescent serum intramuscularly or intrathecally—is still more or less experimental. The results of serum treatment are encouraging, but serum appears to be chiefly valuable in the pre-paralytic stage, and, except in epidemics, is not likely to be available. Efficient local treatment is, therefore, at present the first consideration.

Except in cases with severe fever, in which some delay is justifiable, local treatment should commence as soon as the paralysis is manifested. Massage, and active, passive, and electrically stimulated movements at this stage are painful and harmful, rather than beneficial. Treatment consists, therefore, of rest and prevention of stretching of the paralysed muscles and prevention of deformity. These objects are attained by splintage, the principle of which is relaxation of the paralysed muscles. When a single muscle or group is affected the position of fixation is that in which the muscle or group is fully relaxed: thus in paralysis of the anterior tibial group the foot is fully dorsiflexed. If antagonists or all the muscles around a joint are affected the joint is fixed in the "neutral" position, or else in that position which protects the most important group of muscles. Thus the foot is dorsiflexed to a right angle; the knee extended but not hyperextended; the hip in neutral rotation, slightly abducted and extended but not hyperextended; the spine straight and hyperextended; the shoulder abducted to a right angle and externally rotated; the elbow flexed to 90 degrees; the forearm supinated; the wrist dorsiflexed; and the fingers straight. The position is best maintained by plaster-of-Paris, applied with the aid of an anaesthetic if necessary. In the absence of facilities for application of plaster, recourse may be made to splints of metal or other material. Plaster has the advantages of imposing absolute immobility and of needing little attention.

Immobilization should continue for two months. So long a period as this may not be necessary in every case, but it is a good general rule in view of the danger of too early movement. There is no risk of ankylosis of joints or hopeless atrophy of muscles. At the end of two months the plaster should be removed, and the parts examined clinically and by faradic and galvanic stimulation to determine the extent of the residual paralysis. Not infrequently there is a surprising amount of recovery. Active movements, massage, faradic and galvanic stimulation, and other measures aiming at the return of power and improvement of the nutrition of the affected parts may now be commenced. Splintage should be continued, and apparatus to prevent deformity and protect the recovering muscles may need to be ordered. By this time, however, arrangements will probably have been made for expert attention to the case. My purpose here is merely to describe the immediate local treatment of an acute case, and to emphasize its importance.—I am, etc.,

Bournemouth, Aug. 24th. N. ROSS SMITH, F.R.C.S.

TONSILS AND ADENOIDS IN HOSPITAL PRACTICE.

SIR,—The necessarily condensed report of the discussion, and consequent telescoping of two of my sentences, has given Dr. R. R. Simpson (August 24th, p. 368) a somewhat erroneous impression of what I said at the meeting of the Section of Diseases of Children at Manchester. It is one of the glories of British surgery that the poorest hospital patient has resources placed freely at his disposal which can be obtained by comparatively few private patients, and that at great expense. The team work during the recent illness of the King has evoked the admiration and, indeed, the envy of the world; but every doctor in this country knows that a team almost equal in numbers and in skill is available at most general hospitals for the poorest patient.

What I called at Manchester "a disgrace to British surgery" is the fact that there is to-day one operation—the removal of tonsils and adenoids in children—in which hospital patients are treated very much worse than private patients. I confess that when I was formerly in charge of an out-patient clinic for tonsil and adenoid operations it used to lie heavily on my conscience that those children on whom I had operated would be sent back in an hour or two to their poor and often crowded homes, usually on an omnibus. It is true that only young children were operated upon; they were inspected before they left the hospital; next day they were visited by a nurse; and it is also true that serious complications were rare; nevertheless, our private patients are treated very differently. I used to salve my conscience, as Dr. Simpson does, by reminding myself that the operations were necessary, beds were not available, and that it was probably better to treat them in this way than not at all.

I insisted at Manchester that the time had now come when we surgeons, who have the duty of performing these operations, ought to compel hospital authorities and local authorities, who require the operations to be done, to provide proper accommodation for these children. That accommodation need not be elaborate: the children require comparatively little in the way of food or nursing, but they do require beds, or a least couches, to lie upon, and a roof to lie under, for a minimum of forty-eight hours. The resolution which I drafted and which was unanimously adopted at Manchester expresses this sufficiently plainly; but similar resolutions have been passed before without much effect.

I regret all the more, therefore, that Dr. Simpson should argue in favour of the present state of affairs. My whole point is that if he and others similarly situated will insist that these operations on children should no longer be treated as out-patient operations, the hospital and local authorities must provide the proper accommodation. In the old tonsillotomy days (before 1910) it did not matter so much, for tonsillotomy was not much worse than a tooth extraction; and the institution of these out-patient clinics dates from this period. But the modern operative procedure of complete enucleation of the tonsils and removal of adenoids is a very different affair, and I think that surgeons in charge of hospital and school clinics should present a united front on the matter.—I am, etc.,

London, W., Aug. 25th. R. SCOTT STEVENSON.

PREVENTION OF TUBERCULOSIS OF BOVINE ORIGIN.

SIR,—In the *Journal* of August 24th (p. 366) Dr. Frank Bodman makes the following statements.

"1. That the elimination of tuberculous animals from dairy herds is impracticable.

"2. That in spite of recent preventive measures (13,800 cows were slaughtered in 1928), there is still a widespread infection of the milk supply with tubercle bacilli in some areas.

"3. That such infection, rather than decreasing, is slightly increasing.

"4. That probably nearly 2,000 infants die of bovine tuberculosis each year, and that several millions sterling are expended annually in the treatment, convalescence, and after-care of the survivors."

At a meeting of the Guildford Division of the British Medical Association in 1927, Dr. Nathan Raw stated that in several large American towns all milk was pasteurized. In these towns bovine tuberculosis was unknown, and, in order to teach the students at the medical schools, cases of bovine tuberculosis had to be imported from the parts of the country where the milk was still not pasteurized.

In 1898, my father, at that time principal medical officer of the Local Government Board, when delivering the Harben Lectures before the Royal Institute of Public Health on the "administrative control of tuberculosis," stated: "I cannot take upon myself the responsibility, when speaking of the relation of milk to human tuberculosis, to pass over in silence a means of absolute and certain prevention which every householder has at his or her own disposal—I refer to the boiling, sterilizing, or 'pasteurizing' of milk."

The Royal Commission in 1890 reported as follows: "The most deadly tuberculous material can be rendered absolutely innocuous, in so far as any spreading of infective disease is concerned, by the action of a temperature at which water boils." "It is sufficient to state that boiling

for an instant even renders the tubercle bacillus absolutely innocuous."

Yet the years go by, and the general practitioner is constantly faced with the toll of disease and death caused by bovine tuberculosis. Is it surprising that we medical men wonder why action is not taken by the Ministry of Health to stop this deplorable condition of affairs? One cannot help saying with the late King Edward, "If preventable, why not prevented?" Is it possible that we think more of vitamins than of the health and life of the children?—I am, etc.,

London, W., Aug. 26th. RICHARD THORNE THORNE.

X-RAY DEPARTMENT DANGERS.

SIR,—In your issue of August 17th (p. 317) there is a reference to the danger of valve tubes of *x*-ray apparatus themselves emitting *x* rays, as though this were a new fact. I believe I was the first to mention this danger in vol. 3, p. 126, of my *Theory and Practice of Radiology* quite eighteen months ago, before any valve *x*-ray apparatus was manufactured in England, and when using the first example of this apparatus installed in England for private practice.

The emission of *x* rays by such an apparatus shows that it is being operated without adequate knowledge of thermionic valve theory, since, if the filament has an adequate electron emission, the voltage drop across the valve tube is only about 1,000 volts or less, and much less than that which can excite any *x* rays able to pass through the glass envelope. It is only when the valve tube is wrongly operated at too low a filament value that, space charge being decreased, the electrons are able to obtain sufficient velocities (owing to the larger voltage drop) to excite penetrating *x* rays, and in this case not only is the valve tube at fault, but the *x*-ray tube itself is then affected, as the available applied voltage is then less than by correct operation. That such effects can occur by misuse is another argument to show the mere possession of an *x*-ray apparatus does not constitute a radiologist.

Your suggestion that the valve apparatus should be placed in a separate room immediately robs this type of machine of its only advantage—namely, noiselessness. While valve apparatus looks pretty and is at present the mode, it has no advantage, other than noiselessness, over the older mechanical rectifier, which is simpler to operate, more reliable, and cheaper to maintain, has no expensive valves, and gives a more efficient spectral emission of *x* rays. The mechanical rectifier, if placed in a separate room, has all the benefits of noiselessness, and, copying German installations, I did this in England at the East London Hospital some years ago.

I would take this opportunity to point out a danger in the *x*-ray department which has not yet been appreciated by the protection committees. At a fairly large hospital recently built near London, I am informed that the most conspicuous *x*-ray feature is the lead-lined walls, floors, and roofs. This hospital's installation has, I believe, complied with all the National Physical Laboratory's requirements. It has, however, apparently not been recognized that, in the event of fire, molten lead is very disconcerting, to say the least. If lead were the only protective material there would be some excuse for its use, but since Kampe and Lorey introduced barium sulphate as an *x*-ray building material, Barclay has used barium plaster with success at Manchester, and I have introduced it as concrete with steel reinforcement for large structures at the East London Hospital. Still more recently it was employed at Edinburgh. With protective power dependent on mass, barium cement is about £6 per ton as compared to sheet lead at £60 to £80 per ton. At Victoria Park the architect's estimate for lining the *x*-ray room with lead at £300 to £400 (based on the recently built hospital already mentioned) was, at my suggestion, reduced to an outlay of perhaps £30 to £40 by use of barium plaster. With this plaster there is no danger of metallic short circuit of higher tension leads and possible injury or of static effects due to condenser action of sheet lead; while, in case of fire, the material is incombustible, whereas lead is rendered molten and very dangerous.—I am, etc.,

Forest Gate, E., Aug. 18th. BERNARD LEGGETT.

TROPICAL DIETARIES.

SIR,—I have been making some investigations into the subject of tropical dietaries, and wish to gain as much information as possible with regard to the following points:

1. What is considered an optimum calorie value for various classes of labour in the tropics?
2. The proportion of proteins, carbohydrates, and fats in such a dietary.
3. The analysis of local foodstuffs.
4. The vitamin content of dietaries in use, especially with regard to vitamins A and D.
5. The presence, if any, of diseases due to avitaminosis among peoples on the dietaries named.

I should be grateful for any information you or your readers can give me on these lines with regard to dietaries in use in hospitals and prisons in their territory.—I am, etc.,

J. NEIL LEITCH,
Government Pathologist, Sierra Leone, West Africa.

Freetown, Aug. 6th.

MEDICAL WOMEN AND THE BOARD OF CONTROL.

SIR,—It may be of interest to the members of the British Medical Association who have read the recent correspondence in your columns under the heading "Medical Women and the Board of Control" (August 10th and 17th) to know that this subject is one on which the Medical Women's Federation holds definite views, and on which it has made an official pronouncement. The following is a brief summary of the evidence which was submitted on behalf of the Federation to the Royal Commission on Lunacy in January, 1925.

"The Medical Women's Federation submitted that at least one of the members of the Board of Control should be a fully qualified medical woman with previous experience in the care and treatment of mental disease. The advantages from the point of view of the patient, the public, and the Board of Control were summarized, and the fact emphasized that there is a greater number of females than males amongst mental cases, and that for this reason the opportunity of consulting a medical woman should be provided. It is not the question of providing medical women for all the women patients, but of having one available on the Board of Control to advise on those special cases which constantly occur amongst women of all ages under its jurisdiction.

"There is undoubtedly a demand by the relatives of the insane for a medical woman's advice, more particularly in cases of puberty and adolescence and at the climacteric.

"Other departments of the Ministry of Health have accepted the principle that medical women are desirable, and it is felt that there is at least as great a necessity among patients suffering from all forms of mental diseases. The fact that there are already two women Commissioners does not affect the point at issue.

"The desire is to have a woman as well qualified as her male colleague, appointed to sit on the board, in addition to any and all of its present members. Even if more than one medical woman were appointed, there would not be an undue representation of women on the Board."

—I am, etc.,

VIOLET KELYNACK,
Medical Secretary, Medical Women's Federation.

London, W.1, Aug. 26th.

FEES FOR ATTENDANCE ON DIFFICULT LABOUR.

SIR,—May I point out some of the anomalies in fees allowed to practitioners sent for by midwives? If the doctor is present at the crucial moment of parturition two guineas are allowed, and another guinea if he can get a second doctor to give a slight anaesthetic. He is entitled to this fee even if he does not pay another visit. For the combined services of arresting post-partum haemorrhage, suturing the perineum, and attendance on the mother for sepsis and the child for ophthalmia, dermatitis, etc., for the first ten days one guinea only is allowed, even though he may have to pay two or three visits a day. If there was no haemorrhage or ruptured perineum to attend to in the beginning, then a fee of 5s. a visit, or 10s. at night, is allowed for any slight ailment of mother or child, and for ten days a minimum fee of £2 10s. can be claimed for a daily visit. I fail to see the logic of this scale of fees.—I am, etc.,

M. P. K. MENON, M.B.

London, N.9, Aug. 23th.

Obituary.

FLETCHER BEACH, M.B., F.R.C.P.,

Consulting Physician, Society for Promoting the Welfare of the Feeble-minded.

WE regret to record the death, on August 18th, at the ripe age of 84, of Dr. Fletcher Beach, consulting physician to the West End Hospital for Nervous Diseases.

Fletcher Beach was born at Bridport, Dorset, on March 9th, 1845, and from Dorchester Grammar School went to study medicine at King's College, London. After obtaining the diploma of M.R.C.S. in 1868, he graduated M.B.Lond. in 1874, and was elected F.R.C.P.Lond. in 1880. Having held several hospital appointments, he was attracted to the study of mental science, and became resident assistant physician to the Bethlem Royal Hospital. Subsequently he was appointed by the Metropolitan Asylums Board to be medical superintendent of its schools for imbecile children at Darenth, which he organized, after a visit to the principal institutions for mental defectives in the United States in 1876. Dr. Beach retained this post for about twenty years, and on his retirement took up consulting practice in London, when he was appointed physician to out-patients at the West End Hospital for Nervous Diseases and physician to the Chalfont Colony for Epileptics. In 1895 he was promoted full physician to the West End Hospital for Nervous Diseases, and senior physician in 1906. When in 1907 he resigned for reasons of health he was elected consulting physician to the hospital, an appointment which he held till the time of his death. He did valuable work as consultant to the National Association for the Feeble-minded, and took a prominent part in the various philanthropic efforts for making suitable provision for mental defectives, which culminated in the passing of the Mental Deficiency Act of 1913. Dr. Beach had previously been a member of the committee of experts, appointed on the motion of the late Dr. Francis in the Section of Psychology of the Annual Meeting of the British Medical Association in Glasgow in 1888, for the scientific study of the mental and physical condition of childhood, which did much to enlist public interest in the need for special instruction and the medical inspection of children in elementary schools. In 1874 he joined the Medico-Psychological Association and took an active part in its proceedings, serving as secretary of its Parliamentary Committee for ten years and as general secretary from 1889 to 1896; he was president of the society in 1900. He was also a corresponding member of the Société de Psychiatrie de Paris and an associate member of the Société de Médicale Psychologique de Paris. On his retirement Fletcher Beach went to live at Coulsdon, Surrey, and in 1914, notwithstanding his advanced age, he joined the staff of the Cane Hill Mental Hospital, Coulsdon, where he worked for the duration of the war.

Dr. Fletcher Beach became a member of the British Medical Association in 1882, and was a frequent attendant at the Branch and Annual General Meetings. He was secretary and vice-president respectively of the Section of Psychology in 1892 and 1894, when the Association held its Annual Meetings at Nottingham and Bristol. He was also a member of the Parliamentary Bills Committee and of the Lunacy Subcommittee thereof. He was president of the Thames Valley Branch in 1901–2. He was often to be seen at the meetings of the International Medical Congress, and possessed a large circle of American and Continental medical friends, who appreciated his geniality and kindness of heart. To his love of foreign travel he added a zest for Alpine climbing, an activity which occupied much of his leisure in his earlier days. He was a frequent contributor to our columns in the past. Among his many published writings may be mentioned a succinct treatise on the *Treatment and Education of Mentally Feeble Children* (1895), articles on the pathology and treatment of idiocy and imbecility in Hack Tuke's *Dictionary of Psychological Medicine* (1892), and on the whole subject of idiocy and imbecility, jointly with the late Dr. G. E. Shuttleworth, in Allbutt and Rolleston's *System of Medicine* (1910). He also contributed an article on cretinism to the second edition of Quain's *Dictionary of Medicine*. Numerous papers from his pen have appeared in the *Journal of Mental Science*.

Dr. Beach was twice married. His only son served in the Dardanelles and Palestine campaigns, and was awarded the D.S.O., but succumbed to influenza when recovering from a severe wound sustained in action.

DR. RAPHAEL BELILIOS, who died on June 19th at Shanghai, in his fifty-sixth year, received his medical education at Edinburgh, where he graduated M.B., Ch.B. in 1901; he obtained the diploma F.R.C.S.Ed. in 1903, and proceeded M.D. with honours in 1905, shortly afterwards gaining the diploma of the London School of Tropical Medicine. After a brief period of practice at Muswell Hill, during which he was also engaged in the study of ophthalmology, he went out to Hong-Kong, where he soon built up a large general practice, and was appointed lecturer and examiner in anatomy and physiology in the Hong-Kong School of Medicine. In 1912, having decided to devote himself entirely to ophthalmic surgery, he moved to Shanghai; he was appointed lecturer, and later professor of ophthalmology, in the St. John's University of Shanghai, and ophthalmic surgeon to St. Luke's Hospital. When the British Defence Force arrived at Shanghai in 1927 he was appointed its consulting ophthalmologist, and his work earned the high esteem of his army medical colleagues. At the time of his death he was recognized as one of the leading authorities on diseases of the eye in the Far East. He was a member of the British Medical Association. Dr. Belilios is survived by his wife. In the course of an appreciatory reference, Dr. B. H. S. Aylward, port health officer, Shanghai, writes: The most lovable trait of Raphael Belilios was his boyish enthusiasm, which he retained to the end of his life. He was also the most generous of men, always ready to help a fellow being without criticizing him. It was difficult for him to say a bad word about anybody; if he could not say a good word he preferred to say nothing. I was with him as a student, and he was certainly one of the best of his year. He seemed to relish examinations, and was never satisfied unless he headed the list. On the rare occasions I met him after we were students together at Edinburgh and before he had left England, I made a practice of using him as an encyclopaedia of medicine and surgery; he would often from memory tell me the number of a page in a book where I could find what I wanted, as well as give me the information itself. In Raphael Belilios we have lost a most generous gentleman and a brilliant colleague.

WE regret to report the death of Dr. P. C. WOOLLATT, who was killed in a motor accident while touring in Brittany. Percy Charles Woollatt received his medical education at the London Hospital, Edinburgh, Brussels, and Vienna. He obtained the diplomas M.R.C.S., L.R.C.P. in 1905, graduated M.D.Brussels in 1910, and five years later became F.R.C.S.Ed. The greater part of his professional life until 1920 was spent in Persia, where he held an appointment in connexion with the Indo-European Telegraph Department at Shiraz; in consequence of his outstanding surgical skill he became, early in his career, medical superintendent of the Indian Government Hospital in that town. He was also surgeon to the Imperial Hospital, Teheran. His surgical ability secured for him great popularity, which served him well when the Bolshevist invasion necessitated the withdrawal of English residents in Persia. During the war he held a commission as surgeon in the Royal Navy, and he was also surgeon to the South Persian Rifles while that force existed. In 1920 his health compelled him to retire from his Persian appointments, and he returned to England and carried on a consulting practice in London. His skill in diagnosis and operation won him the high esteem of his colleagues and patients; a certain bluntness of manner failed to conceal a very warm-hearted disposition. He was a member of the British Medical Association.

DR. JAMES DOUGLAS WRIGHT, who recently died after a short illness at the age of 44, received his medical education in Glasgow, and obtained the diplomas L.R.C.P., L.R.C.S. Ed. and the L.R.F.P.S.Glas. in 1912. During the war he held a commission as captain in the Royal Army Medical Corps, and served in France. He then engaged in post-graduate work, and obtained the F.R.F.P.S.Glas. in 1921. He subsequently practised at Wembley Park, where he earned considerable reputation as a physician and for midwifery. A colleague writes: The late Dr. D. Wright was one of the old school of practitioners, who took an immense interest in the welfare of their patients. He was always endeavouring to keep himself thoroughly conversant with modern work, while his wide experience gained for him a reputation in the neighbourhood of Wembley Park. His quiet, kindly manner made him loved and respected, both by his patients and colleagues.

DR. THOMAS WILLIAM BUCKLEY, who died on August 8th, aged 70, received his medical education at St. Thomas's Hospital and Owens College; he obtained the diploma L.S.A. in 1882 and the M.R.C.S.Eng. in 1883, graduating M.D.Durham in 1900. He acted for a time as assistant to his uncle, Dr. Thomas Morton, and was assistant house-surgeon at the Staffordshire County Infirmary and surgeon on one of the vessels of the Ocean Steamship Company. While holding the last appointment he made his only written contribution to medical literature: "Novel method of delivery at sea" (*British Medical Journal*, 1885, vol. ii, p. 344). In 1888 he bought a practice at Thrapston, Northants, and in partnership with the late Dr. J. W. Gainer worked over a huge rural district for twenty years. He was the local medical officer of health, and a J.P. for Northamptonshire. On the outbreak of war he immediately volunteered for service abroad. Refused at first on account of age, he received a commission in 1915, and was sent to a military hospital at Shoreham. Promoted major later in 1915, he acted for a year as assistant commandant and officer commanding the R.A.M.C. detachment at Princess Christian Military Hospital, Englefield Green. In 1916 he was appointed to No. 2 Special Medical Board, Caxton Hall, ultimately becoming its president. The work was very heavy, involving visits of inspection to hospitals in and around London and many hours of writing reports, as well as the routine work of the board. He was not demobilized till 1919, and never fully recovered from the strain of those years. He spent the rest of his life very quietly in the little village of Clopton, a few miles from the centre of his practice, happy with his books and the interests of country life. Very modest about his own attainments, which were considerable, he had a keen sense of humour, and could tell many interesting stories of his experiences. He leaves a widow, a son, and two daughters, one of the latter being in the medical profession.

DR. REGINALD POMFRET WYLDE, who died on August 17th after a short illness, was born in 1879. He received his medical education at Manchester, and obtained the diploma L.M.S.S.A.Lond. in 1910. He had conducted a medical practice in Hollingworth, Cheshire, for the last nineteen years, during four of which he assisted his late uncle, Dr. Pomfret, to whose practice he succeeded. Dr. Wylde held the appointments of medical officer of health of Hollingworth and medical officer and public vaccinator for the eighth division of the Ashton-under-Lyne Union. His funeral service on August 19th was held at Tintwistle parish church; it was attended by members of the public bodies with which he had been associated, and by his medical colleagues, by whom he was held in high esteem. Dr. Wylde was a member of the Glossop Division of the Lancashire and Cheshire Branch of the British Medical Association.

The following well-known foreign medical men have recently died: Professor DOMINIK PUPOVAC, an eminent Vienna surgeon, of relapsing pneumonia; Professor CARLO FRANCIONI, director of the paediatric clinic of Bologna; Dr. LEVY-DORN, one of the pioneers of roentgenology in Germany, and until recently director of the Roentgen Institute of the [illegible]; Dr. PAUL SOBOTKA, a Prague dermatologist; Dr. CHARLES MOREU, member of the Académie de Médecine, professor at the Collège de France, and grand officer of the Légion of Honour; Geheimrat OTTO BINSWANGER, formerly professor of neurology at Jena; Professor P. FLECHSIG, the Leipzig psychiatrist, aged 82; Dr. JOSEF SZABO, professor of neurology and psychiatry at Szeged (Hungary); Professor CARL HUETER of Marburg University, aged 68; Dr. HENRI REYNÈS, professor at the medical school of Marseilles; and Dr. NAFIZ PASHA, emeritus professor at Constantinople, the oldest physician in Turkey, and author of the first Turkish textbook on general pathology, aged 91.

THE LATE SIR THOMAS SMARTT.

SURGEON CAPTAIN H. B. BEATTY, R.N.(ret.), writes: In the *Journal* of June 22nd (p. 1138) its South African correspondent, writing appreciatively of the late Sir Thomas Smartt, remarks that it was very difficult to imagine what induced him to take up farming in the arid area around Britstown, and that his contribution to the development of South Africa as a scientific farmer is by some considered to be as valuable as his statesmanship. The explanation is, I think, afforded in a letter written by him to me, now forty years ago, when I was serving in a gunboat on the Cape and West Coast of Africa station. In this letter he invited me to pay him a visit at his home in the Karoo country (an invitation which unfortunately I was unable to accept). He stated that his fees were mostly received in the form of livestock, as the Boer farmers possessed very little actual money. Struck by the advantage that would accrue to him by improving the breed of sheep, he was then procuring, as a beginning, a couple of merino rams from Australia (or Tasmania). He was also corresponding with Australia concerning irrigation systems, a larger and more equable water supply being necessary for successful farming and stock raising in both countries. His actions in the circumstances, more or less forced on him thus early in his life in South Africa, showed the same breadth of outlook that characterized him in his subsequent distinguished career.

Universities and Colleges.

SOCIETY OF APOTHECARIES OF LONDON.

THE following candidates have passed in the subjects indicated:

SUR[illegible] Bhattacharyya, A. Clark, [illegible]es, J. E. Moody, C. Partha[illegible]s.

MID[illegible] Kapur, N. H. Kettlewell, W. McDermott, R. Norris, E. J. O'Loughlin, A. W. Tam.

FORENSIC MEDICINE.—K. C. Bhattacharyya, W. T. Ellis, B. L. Fishout, W. M. Hamer, J. M. Lees, C. A. Munro, E. J. O'Loughlin, S. Ramadas.

MIDWIFERY.—J. Britanischski, R. Gilmore, W. St. A. Hendricks, C. Hortop, J. M. Lees, A. R. Madden, A. Somerville, F. A. Yarde.

The diploma of the Society has been granted to Messrs. B. L. Fishout, N. H. Kettlewell, H. H. Lakin, J. M. Lees, C. Partharsarthe, and A. W. Tam.

Medical News.

SIR JOSIAH STAMP, G.B.E., will deliver the thirteenth Norman Kerr Memorial Lecture before the Society for the Study of Inebriety, on October 8th, at 4 p.m., in the Great Hall of the House of the British Medical Association, his subject being "Alcohol as an economic factor." Each member and associate is free to introduce visitors.

AT the tenth annual lecture conference of the Industrial Welfare Society, which will be held in Oxford from September 13th to 17th, Dame Louise McIlroy will read a paper on the health of women in industry, and Dr. D. A. Coles will discuss health problems in industry.

THE winter session at the Middlesex Hospital Medical School will open on Tuesday, October 1st, when an introductory address, entitled "Life's endless chain," will be delivered at the Queen's Hall, at 3 p.m., by Dr. E. A. Cockayne, after which the prizes and medals gained by students and nurses will be distributed by Mr. S. A. Courtauld. The annual dinner will be held on the evening of the same day at 7.30 p.m., at the Savoy Hotel, when the chair will be taken by Mr. A. E. Webb-Johnson, C.B.E.

A POST-GRADUATE course in methods of examination and diagnosis will be held at the Central London Throat, Nose and Ear Hospital, Gray's Inn Road, W.C.1, on the following afternoons at 1.30: September 23rd, the ear; 25th, the nose; 30th, hearing-tests; October 2nd, the sinuses; 7th, the mouth [illegible]

THE Fellowship of Medicine announces that an all-day course in diseases of the chest will be held at the Brompton Hospital from September 9th to 14th. From September 9th to 22nd there will be a course in diseases of infants at the Infants Hospital. A series of lecture-demonstrations in psychological medicine will be given at the Bethlem Hospital from September 10th to October 5th, on Tuesday and Saturday mornings at 11 a.m. An intensive course in medicine, surgery, and the specialties will be held at the Westminster Hospital from September 16th to 28th, during the mornings and afternoons, open to men only. There will be a cor 'he Prince of Wales's General the North Middlesex Hospital 30th to October 4th. Courses in October include: cardiology at the National Heart Hospital, October 7th to 18th; ophthalmology at the Central London Ophthalmic Hospital, October 7th to November 2nd; tropical medicine at the London School of Tropical Medicine, on Tuesdays and Thursdays from October 8th to 31st; gynaecology at the Chelsea Hospital, October 14th to 26th; diseases of children at the Great Ormond Street Hospital, October 14th to 26th; and diseases of the throat, nose, and ear, at the Central London Throat Hospital from October 14th to November 2nd. The Metropolitan Hospital will hold its first course under the auspices of the Fellowship from October 21st to November 2nd; it will comprise intensive instruction in medicine, surgery, and the specialties, and will be planned particularly for panel practitioners and others. In view of the success of the first M.R.C.P. course arranged by the Fellowship it is proposed to hold another course from October 15th to December 6th; the lectures will be delivered on Tuesdays and Fridays at 8.30 o'clock in the lecture hall of the Medical Society of London, 11, Chandos Street, Cavendish Square, W.1. Detailed syllabuses of the above courses, information regarding the general course arranged by the Fellowship in connection with its associated hospitals, and copies of the Fellowship *Journal* are obtainable from the Secretary of the Fellowship, I, Wimpole Street, W.1.

THE Medical Research Council has received from Mrs. Odo Cross a sum of £40,000 as the endowment of a trust for the establishment of research fellowships in the study of tuberculosis, to be known as the "Dorothy Temple Cross Research Fellowship Fund."

A CONGRESS will be held at Evian-les-Bains on September 14th and 15th, under the presidency of Professor Carnot of Paris. Lectures will be given by Professors Villaret and Lemierre of Paris, Professor Roch of Geneva, Professor Pic of Lyons, and Dr. Halls Dally of London. The congress will be followed by an excursion to Chamonix from September 16th to 18th. Further information can be obtained from the general secretary, Mlle Machuré, Rue de Londres 21, Paris.

THE Garrick Theatre production of *The Lady with a Lamp*—a play with Florence Nightingale as the central figure—is being taken to the principal suburban and provincial theatres before visiting the Dominions overseas.

THE official report of the fifth International Congress of Military Medicine and Pharmacy, which was held in the House of the British Medical Association in May, has now been supplied to those who took part in the proceedings. It contains reprints of the photographs of the members and delegates which were taken on that occasion; some of the papers read are reproduced, and summaries are given of the remainder.

WE are informed that the Deshell Laboratories Limited has changed its name, and is now to be known as the Petrolagar Laboratories Limited. There has been no change in ownership or management.

THE sum of 100,000 francs has been presented by M. Guy Amerongen to the French League against Cancer, with a view to encouraging research into the question whether preserved foods or chemicals have any influence in producing malignant disease. A prize is to be offered each year for an essay on this subject, which must be sent in before October 1st. An international scientific committee has been appointed, Mr. Sampson Handley being the British representative. Further information may be obtained from the League, 2 Avenue Marceau, Paris VIII^{e}.

THE seventh volume of the Guide to Current Official Statistics of the United Kingdom, which has just been published, affords a systematic survey of the statistics appearing in all official publications issued in 1928. Furthermore, in relation to each publication the Guide gives an account of the nature of the statistics therein found, their mode of analysis, and the time and place to which they relate. It is printed and published by H.M. Stationery Office, and costs 1s.

DR. RECASENS, professor of gynaecology and dean of the faculty of medicine, has been elected president of the Academy of Medicine of Madrid and of the Spanish Gynaecological Society.

Letters, Notes, and Answers.

All communications in regard to editorial business should be addressed to ***The EDITOR, British Medical Journal, British Medical Association House, Tavistock Square, W.C.1.***

ORIGINAL ARTICLES and LETTERS forwarded for publication are understood to be offered to the *British Medical Journal* alone unless the contrary be stated. Correspondents who wish notice to be taken of their communications should authenticate them with their names, not necessarily for publication.

Authors desiring REPRINTS of their articles published in the *British Medical Journal* must communicate with the Financial Secretary and Business Manager, British Medical Association House, Tavistock Square, W.C.1, on receipt of proofs.

All communications with reference to ADVERTISEMENTS, as well as orders for copies of the *Journal*, should be addressed to the Financial Secretary and Business Manager.

The ***TELEPHONE NUMBERS*** of the British Medical Association and the *British Medical Journal* are *MUSEUM 9861, 9862, 9863,* and *9864* (internal exchange, four lines).

The ***TELEGRAPHIC ADDRESSES*** are:
EDITOR of the *British Medical Journal, Aitiology Westcent, London.*
FINANCIAL SECRETARY AND BUSINESS MANAGER (Advertisements, etc.), *Articulate Westcent, London.*
MEDICAL SECRETARY, *Mediscen Westcent, London.*

The address of the Irish Office of the British Medical Association is 16, South Frederick Street, Dublin (telegrams: *Bacillus, Dublin*; telephone: 62550 Dublin), and of the Scottish Office, 7, Drumsheugh Gardens, Edinburgh (telegrams: *Associate, Edinburgh*; telephone 24361 Edinburgh).

QUERIES AND ANSWERS.

TREATMENT OF MYASTHENIA GRAVIS.

"F. H." asks for suggestions for the treatment of myasthenia gravis in a woman aged 23. Periods of rest, ranging from three weeks to two months, have been tried without permanent benefit. Pituitrin injections, thyroid and parathyroid extracts, calcium, and mild tonics have all been tried without much result. After rest in bed her leg muscles improve, but her swallowing ability and the upper extremity muscles do not.

SPECIFIC GRAVITY OF THE BODY.

DR. W. JOBERNS (Wolverhampton) asks for the following data about the male and female body, and that of the young child: (1) the specific gravity of the body as a whole; (2) the specific gravity of the head; (3) the specific gravity of bone; and (4) the weight of the head. He also wishes to know what weight a swimmer, whether male or female, can support without being submerged.

INFECTION IN PUBLIC BATHS.

DR. HUGH DONOVAN (Birmingham) writes: In the consideration of nasal and aural disease resulting from bathing in city baths, the hypotonic action of water on the nasal mucosa does not seem to have been sufficiently stressed. There are obviously two factors in the production of these diseased conditions—trauma and infection. In my own case I am impressed with the fact that I am very likely to get a recrudescence of chronic nasal infection when I bathe in fresh water. Is it a practical possibility to fill public swimming baths with normal saline in place of plain water?

A SUITABLE EUROPEAN RESORT FOR AN ALBUMINURIC PATIENT.

"J. B. D." asks for suggestions as to a suitable neighbourhood in south Europe where a native of India, who is about to retire at the age of 55 from the Government service in that country, may settle down. During his period of service he led a very strenuous life, at times in the hottest places in the Bombay Presidency. For the last three years albuminuria has been present, ranging from a trace to about 0.25 per cent. or more. The blood pressure, estimated about a year ago, was not above the normal for his age. He is otherwise in good health, moderate in habits, and very active. "J. B. D." asks if the albuminuria is likely to increase if the patient begins his residence even somewhere in the south of Europe in winter for the first time. Would it be more advisable for him to settle in some place in India where the climate is more equable all the year round? If there is no contraindication to his living in Europe, "J. B. D." would be glad to have the names of suitable places.

STERILE MILK INJECTIONS.

DR. JOHN DONALD (Glasgow) writes: Can you tell me whether there is danger in giving intramuscular injections of sterile milk for such conditions as chronic suppurative otitis media?

*** An article by Dr. Hassan Bey Shaheen, aural surgeon, Kasr-el-Aini Hospital, on the treatment of chronic otitis media by subcutaneous or intramuscular injections of sterile milk, appeared in our issue of April 6th at page 643.

RATIO OF HOSPITAL BEDS TO LOCAL POPULATION.

"INQUIRER" asks for information as to the number of hospital beds which it is advisable to provide for a given population.

*** In the final report (1928) of the Voluntary Hospitals Commission it is stated that at the time of the 1924 survey the ratio of beds to population was 1.33 per 1,000. This ratio was

based upon a figure of accommodation which, in the opinion of the Commission, was 10,000 beds short of what was reasonably necessary. If this deficiency had not existed the ratio of beds to population would have been 1.6 per 1,000, and the Commission thought that this represented the rate at which the hospitals should expand to keep pace with the growth of population.

TREATMENT OF A STRAINED LEG.

MR. PAUL BERNARD ROTH (London, W.1) writes: In reply to the question of "V. S." on July 27th (p. 171), I think it probable that he ruptured his tendo Achillis right across. Even with a large gap in this tendon the foot can function fairly well because there is a strong sheath which escapes rupture. Until, however, the parts are brought together and sutured the patient can never have a strong foot.

PRURITUS AFTER MUMPS.

DR. F. S. D. HOGG (Rickmansworth) writes: I would suggest that Captain Greenway should try calcium lactate gr. xv three times a day just before or after meals; I have found this most effective in generalized pruritus. A few months ago I had an attack of this trouble myself. One 12 oz. bottle cured the itching, but I took occasional doses of the drug for several weeks. A little syrup aurantii or infusion of gentian covers the slight taste of the calcium, which should be dispensed in very hot water, so as to obtain a solution free from sediment.

INCOME TAX.

Adjustment on Retirement.

"V. F. F." bought a half share in his practice as from May 1st, 1925. For the year to April 5th, 1926, he was assessed for half the average profits of the practice for the then previous three years, calculated on the basis of cash receipts. Accounts were not sent out that year until September, 1925, which resulted in his cash receipts for his first year being less than the amount assessed on him. He was told that he could not claim any relief, but that he would obtain the corresponding benefit when he retired. This will be as from September 30th of this year, but he is informed that the law has changed, and that for the last period his profits will have to be calculated with some regard to the amount of debts outstanding at September 30th.

*** In the first place "V. F. F." could have made a claim, when he first entered the practice, to have the profits computed on the basis of bookings *plus* increase (or *minus* decrease) in the value of the outstanding debts. Possibly this was not what he then sought. If it was, and if the authorities misled him by informing him that that adjustment could not be made, he has at least a special claim to sympathetic consideration of his case now. But it is not yet quite clear how the authorities propose to deal with the final half-year. If the proposal is to add to the cash bookings the value of the debts outstanding at September 30th, 1925, but *to deduct* the corresponding value as at April 5th, 1925, probably little harm will be done. That is, in fact, the correct method of ascertaining the gross earnings for that half-year, and the deduction of the April debts will probably compensate him for the previous inclusion of his predecessor's cash receipts in the computation for 1925-26.

Temporary Residence in England.

"AUSTRALIAN" arrived in England from Australia on May 9th and left for the Continent on May 28th. He returned to England on July 6th, and expects to leave England for Australia on December 28th. We assume that he maintained no residence in this country before he came in May or in the interval—May 28th to July 6th.

*** He will become liable as resident, though not ordinarily resident, if he spends six months of the financial year commencing April 5th, 1929, in this country. If he carries out his intentions he will be in this country for 195 days—that is, he will have fulfilled the condition of liability. In that case he will be liable to declare as his income—for assessment in so far as it has not paid United Kingdom income tax by deduction—any profits or gains derived in this country, whether from work or investments, and any remittances made to him out of income abroad.

Motor Car Transactions.

"C. M. B." bought his first car in 1921 for £410; he sold it in 1925 for £70 and bought a second car for £175; this was sold in 1928 for £20, when he bought his third car (second-hand) for £250. What sum can he claim "as expenses on the replacements."

*** In our view in such a case as this regard should be had to the maximum expenditure as setting the standard, and that renewal cost is allowable until that amount is exceeded. On that basis the expense chargeable to the year 1928 is the amount of out-of-pocket cost—that is, £250–£20=£230. We suggest that if the inspector of taxes takes the view that the third car was an improvement over the second one, and therefore that only £175–£20=£155 is allowable, then "C. M. B." might point out that, in fact, his claim is one for obsolescence allowance, and that the difference between them—namely, £230–£155=£75—should become the basis of a depreciation allowance for 1929-30 and future years. If that can be agreed the real difference between the two methods may be ignored.

LETTERS, NOTES, ETC.

RELIEF OF PAIN.

DR. HERBERT CARDIN (London, S.W.1) writes: Some years ago I was awakened by an excruciating attack of pain due to diaphragmatic pleurisy. After about four hours of agony I inhaled the contents of two capsules of amyl nitrite; in half a minute I had lost every vestige of pain, and never had even the slightest recurrence. Two pints of foul-smelling pus were removed from my chest some eight weeks afterwards; I had healed and was well five weeks after the operation. Ever since I have given amyl nitrite for pleuritic pain. I have only treated three patients thus, but the results have been so gratifying that I think the method is worthy of trial by doctors. The proper treatment of painful conditions is so important that I would also mention that during the last thirty years I have treated all burns and scalds, in the first instance, with ice or ice-water or tap-water; by this means the pain of even a very severe scald vanishes, and after about four hours does not return. When the pain has completely gone the usual greasy dressings are appreciated by the patient. Those who have had a previous experience of burns and scalds, and been subjected to the dreadful carron oil treatment, have all told me that they would never again have anything but the ice or cold water procedure. The only thing a badly scalded or burnt person needs at once is removal of the excruciating pain; morphine affords partial relief, but cold water or ice applied to the burnt surface cures completely all pain and greatly reduces the amount of shock. A few nights ago a woman burnt her hands very badly while using petrol in a basin to clean her shoes, with the gas fire alight in the room. I at once plunged her hands into cold water until ice arrived; five hours afterwards she was able to take them out of the ice-water totally free from pain, and she has had no pain since. During the time the burnt surface is in cold water there is no pain, but if it is taken out too soon the pain returns. It was the indignation of the fire brigade officials at my use of cold water, rather than their first-aid box of tricks, that made me realize that the first-aid treatment of burns is about as bad as it can be.

HILAR TUBERCULOSIS.

DR. H. G. CALWELL (Belfast) writes: I regret to find that in Dr. D. J. Gair Johnston's article on August 24th (p. 335), and in a leading article in the same issue, the term "hilus tuberculosis" is used. The Latin word is "hilum," which is neuter, and therefore has no part "hilus." I have seen the same error in at least one well-known textbook of medicine, and I hope that it will be corrected before it is perpetuated. Why not speak of "hilar tuberculosis."

THE LIGHTER SIDE OF GENERAL PRACTICE.

SPURRED, it appears, by the lighter vein of some of the contributions to the last page of the *British Medical Journal*, Dr. DOUGLAS MACKAY—who states that he always reads the *Journal* backwards—is writing a series of articles on "The lighter side of general practice" for the *Caledonian Medical Journal*. The victim in one of his stories must indeed have had a sense of humour if he was able to see the lighter side of the situation. He was called on a dark, wet winter's night to a distant cottage on an unapproachable hillside. On asking what the trouble was, he was told that the daughter had been in bed since she was 5 years old with a tuberculous spine, and that the previous doctor had said that she must be watched carefully when she reached the age of 21. "This is her twenty-first birthday, and as she was born at a quarter to two in the morning, we thought you had better see her"! There was more satisfaction to be derived from a patient of Dr. Mackay who had swallowed a penny which had stuck in his gullet. When the coin-catcher was introduced the patient retched violently, and brought up 2s. 8d. (a half-crown and two pennies). His face was a study: he knew about the penny, but the two-and-sevenpence came as a surprise to him. Dr. Mackay garnishes his article with many quoted howlers and malapropisms, from which we learn that *pax in bello* means "freed [illegible]"; that the "Synod of Whitby (A.D. 664) [illegible] shape the tonsil on the priest's head [illegible] at "panel doctors are different from ordinary doctors—they are paid!"

A DISCLAIMER.

DR. W. E. GYE (*The National Institute for Medical Research*) writes: In a Sunday newspaper of August 25th a paragraph appeared concerning my work on cancer; this was repeated in a daily paper on the following day. I wish to disclaim all responsibility for the statements contained in the paragraphs.

CORRECTION.

PROFESSOR R. W. JOHNSTONE calls attention to an error in the report in the *Journal* of August 17th (p. 300) of his contribution to the discussion on surgical tendencies in modern midwifery, held at the Annual Meeting in Manchester. The word "hysterectomy" is three times used instead of "hysterotomy," and this error makes a serious difference in the meaning.

VACANCIES.

NOTIFICATIONS of offices vacant in universities, medical colleges, and of vacant resident and other appointments at hospitals, will be found at pages 42, 43, 44, 45, 48, 49, 50, and 51 of our advertisement columns, and advertisements as to partnerships, as [illegible] 47. [illegible] advertisement [illegible] co[illegible]

EPITOME OF CURRENT MEDICAL LITERATURE.

Medicine.

179. Nerve Complications of Erysipelas.

F. DERRUX and R. GALLÈGUE (*Gaz. des Hôp.*, June 26th, 1929, p. 933) state that, apart from restlessness and more or less violent delirium, which are fairly frequent, nerve complications in erysipelas are exceptional. They have been classified under the headings of meningitis, encephalitis and myelitis, and neuritis and polyneuritis. Only 9 cases of meningitis in erysipelas in which the diagnosis has been confirmed are on record bacteriologically. They are of three kinds. The first and most frequent (6 cases) is that caused by the *Streptococcus erysipelatosus*; the second is due to association of the pneumococcus and streptococcus (2 cases), and the third to the pneumococcus alone (1 case). A few cases of encephalitis have been recorded, but none of these has been confirmed by necropsy. Only two cases of myelitis have been published, in one of which the diagnosis was confirmed by necropsy. A few cases of paralysis of the third and seventh cranial nerves have been recorded, but optic neuritis and atrophy, of which the authors have collected 27 cases, are relatively frequent; 82 per cent. of the cases of optic atrophy ended in permanent blindness. Most of the cases of optic neuritis and optic atrophy have been observed in facial erysipelas, and are the result of the local spread of the infection to the periorbital tissue. Cases of optic neuritis from septicaemia without a local inflammatory stage are very rare. The authors remark that very few cases of polyneuritis attributed to erysipelas can withstand criticism. The rarity of nervous complications in erysipelas accords with the results of experiments on animals, which show that the streptococcus and its toxins have little affinity for the nervous system.

180. Endocarditis in Enteric Fever.

R. SLIT (*Thèse de Paris*, 1929, No. 175), who records eleven illustrative cases in patients aged from 5 to 47 years, states that endocarditis is a very rare complication of enteric fever. It may be due to *B. typhosus* or *B. paratyphosus* A, B, or C, but is most frequently the result of secondary infection. The endocarditis appears in two distinct anatomical and clinical forms—namely, a single benign endocarditis, or as a malignant ulcero-vegetative form. The auscultatory signs are very slight, and the endocarditis remains latent. The dulling of the valvular sounds is difficult to distinguish from that caused by weakness of the myocardial contraction, while murmurs due to changes in the valves are hard to differentiate from functional bruits. It is the rule to meet with signs of cardiac enfeeblement, tachycardia, and an irregular temperature. Death frequently occurs in the acute stage, while in other cases chronic lesions develop.

181. The Occurrence of Glycaemia in Acute Pulmonary Disease.

IN view of the statement that healthy lung tissue has a glycolytic property similar to that of the pancreas, and that in asphyxia there is hyperglycaemia, F. CASTELLOTTI (*Biochem. e. Terapia Sperimentale*, July 31st, 1929, p. 317) has estimated in patients suffering from broncho-pneumonia, pneumonia, and bronchitis the titre of the blood sugar during the course of the illness. The curves showed an early rise in blood sugar, which continued gradually with the extension of the morbid process, attaining a maximum corresponding with the crisis of the illness, and slowly declining to the normal or below it in the stage of resolution. To a patient with bilateral broncho-pneumonia 50 grams of glucose in 100 c.cm. of water was administered by the mouth. The blood sugar curve showed a rapid rise from 1.95 to 2.58 per thousand after thirty minutes, and to 2.75 per thousand after an hour; it fell during the second hour to 2.17 per thousand, and returned after the third hour to slightly below the glycaemic level at starting. Of the ten cases of acute pulmonary disease reported by the author, the blood sugar was raised in every case; in the majority there was no glycosuria.

182. Syphilitic Gastric Linitis.

G. CAUSSADE and G. LEVEN (*Bull. Soc. de Thér.*, June 12th, 1929, p. 146), who record an illustrative case, emphasize the fact that the possibility of gastric syphilis is not sufficiently often considered before undertaking an operation or making a diagnosis of carcinoma of the stomach. The present case was that of a woman who, when 20 years old, contracted syphilis, for which she did not receive a sufficiently long or energetic treatment. At the age of 40 she began to suffer from violent gastric attacks, but without other signs of tabes, and at 47 she had a very profuse haemoptysis. During the next ten years her weight gradually diminished without vomiting, and she had fetid diarrhoea and glycosuria. Death from haemoptysis ensued at the age of 57. The necropsy revealed a trilocular stomach, extensive retroperitonitis, and sclerosis of the pancreas, while microscopical examination showed arteritis of the syphilitic type in the stomach, pancreas, and lung, with aneurysmal dilatations of the vessels in the lungs and stomach. The glycosuria, diarrhoea, and loss of flesh in the absence of vomiting were apparently due to lesions in the pancreas.

183. Sero-fibrinous Pleurisy in Scarlet Fever.

J. SABRAZES and J. J. DUBARRY (*Gaz. hebd. Sci. Méd. de Bordeaux*, June 2nd, 1929, pp. 338 and 373), who record two illustrative cases in women, both aged 32, state that non-tuberculous sero-fibrinous pleurisy in scarlet fever is more frequent in the child than in the adult, being encountered in 1 per 1,000 cases at most in adults and in 5 per 1,000 cases at least in children. In both the authors' cases the effusion occurred in convalescence. Unlike the cell count of tuberculous pleurisy, the cytological formula showed only a small number of lymphocytes. There were about 65 per cent. polymorphonuclear neutrophils, and 30 per cent. large mononuclear elements. As in all complications of scarlet fever, a streptococcus was present. The onset was not insidious, but was accompanied by rise of temperature and diminution of the amount of urine passed. The effusion in each case was of short duration, absorption taking place in eight to ten days. Subsequent *x*-ray examination of the chest in both instances showed no indication of pulmonary tuberculosis.

Surgery.

184. Volvulus of the Small Intestine.

P. BERTRAND and C. CLAVEL (*Lyon Chir.*, May-June, 1929, p. 351) describe a case of volvulus of the small intestine on its mesenteric axis, which occurred in a man, aged 50, who had had a right inguinal hernia for several years. This had not previously caused any troublesome symptoms until the patient experienced a sudden intense abdominal pain accompanied by vomiting and painful tension in the region of the hernia, which was not at this time reducible. On the following day the patient succeeded in reducing it himself, and the pain subsided for a short while, but subsequently the temperature and pulse rate rose rapidly, the whole abdomen became painful, and the faeces contained blood. An operation revealed uniform distension of the small intestine with a complete volvulus and much ascitic fluid in the peritoneum; the mesentery was oedematous and white. The intestine was untwisted, an ileostomy performed, the septic fluid mopped out, and the incision was closed, a large tube being left in. Saline injections were given every four hours, but peristalsis was not re-established and the ileostomy remained dry; vomiting continued incessantly, and the patient died two days later of acute intestinal obstruction. The case was an unusual one in that the principal lesion consisted in the volvulus of the whole of the small intestine on its mesenteric axis from the duodeno-jejunal flexure to the end of the ileum without the involvement of the caecum.

185. Malignant Epithelial Tumours of the Neck.

J. E. MCWHORTER (*Annals of Surgery*, July, 1929, p. 1) emphasizes the difficulty of making a clinical diagnosis in the case of malignant epithelial tumours of unknown origin located in the neck; the usual diagnosis is either Hodgkin's disease, or lymphosarcoma, or sometimes a parotid tumour, or a tuberculous lymph node. Out of 24 cases reviewed 18 patients were men and 6 women, the average age in the former being 50 and in the latter 45. The average duration of symptoms was less than four months, with an extreme variation in one case of two years and in another of one week. Some of the patients showed a bilateral involvement with a ratio of 6 to 18; in a unilateral involvement the left side predominated by 13 to 5. In most cases the tumours arose round the angle of the lower jaw, and in only three cases was there any definite signs of a primary site elsewhere in the body; it is therefore supposed that a certain percentage of these neoplasms arise primarily in the neck from some small epithelial rest. There are no symptoms until the tumour is large enough to be felt; pain occurs in about

50 per cent. of cases and is then severe. Respiratory distress and dysphagia are present when the growth is diffusely infiltrating, and absent when it is circumscribed. The tumour, which is usually in the region of the great jugular lymph node, was generally large, being either smooth or lobulated and of firm, dense consistency, attached as a rule to the deeper structures and only rarely to the skin. When the growth involved both the deep and superficial structures the skin over the surface was red, swollen, and tender, suggesting an abscess rather than malignancy; tenderness may or may not be present. The prognosis is bad, and treatment by excision or radiation seems equally unsatisfactory. The majority of tumours being deep-seated, diffusely invasive, and intimately connected with the great vessels of the neck, require great technical skill if an operation is performed; recurrence is usually rapid and fatal. In a few instances, where the tumour is rather small and encapsulated or circumscribed, it may be a primary growth; excision is then the treatment of choice. In other cases excision would appear to stimulate growth, and radiation is preferable. In nearly every case, however, the tumour when first seen was inoperable.

183. Cholecystectomy.

S. H. MENTZER and J. H. WOOLSEY (*Surg., Gynecol. and Obstet.*, July, 1929, p. 76) discuss recent modifications in the technique of cholecystectomy. It is pointed out that, since the case of all biliary surgery depends upon adequate exposure, the ideal incision must be of sufficient size to admit the assistant's whole hand for retraction and allow space for handling the gall-bladder with modern instruments under direct vision, which may be satisfactorily attained by an ordinary right rectus incision 14 cm. in length. Variations in the duct and vascular arrangements render it imperative that these should be identified accurately, which only an adequate exposure can accomplish, so that the cystic duct can be traced to its junction with the efferent duct. In order to safeguard against leakage the omental edges may be stitched over the stump of the cystic duct after double ligation with the transfixation duct suture to ensure permanent closure. It was found to be possible to close the abdomen without drainage in about 70 per cent. of the cases, but when drainage is necessary this is better through a high stab wound than through the operation incision, thereby offering a better chance for primary closure. Nitrous oxide-oxygen or ethylene anaesthesia in preference to ether is an important consideration when non-drainage is aimed at, since under ether anaesthesia the bile flow is retarded and the finer bile channels may be severed without being recognized, whereas under the nitrous oxide-oxygen or ethylene anaesthesia the activity of the liver is not retarded, and consequently any severed bile ducts can be detected and ligated before closure. It sometimes happens also that upon recovery from ether anaesthesia a biliary peritonitis results as soon as the liver begins to function again.

187. Haemolytic Streptococcus Gangrene.

F. L. MELENEY (*Journ. Amer. Med. Assoc.*, June 15th, 1929, p. 2009), who records two illustrative cases in adults, maintains that haemolytic streptococcus gangrene is a distinct clinical entity, which may occur at any age in either sex. It usually appears in the extremities, but may attack any part of the body. The most important clinical features are the rapid development, profound prostration, and the dusky hue of the skin, with or without blisters or bullae, and usually appearing on the third, fourth, or fifth day. It is distinguished from erysipelas by the fact that the margin is not raised, and usually is not clearly defined. Dark blisters, bullae, and duskiness of the skin usually appear early. The condition differs from ordinary streptococcal cellulitis by the greater rapidity of development, by the rarity of lymphangitis and lymphadenitis, and by the early appearance of the dusky skin or bullae. Treatment consists in long free incision of the skin down to the deep fascia.

188. Surgical Treatment of Angina Pectoris.

S. P. FEDOROFF (*Zentralbl. f. Chir.*, June 1st, 1929, p. 1602), after noting the results obtained by resection of the cervical sympathetic in cases of angina pectoris, and which are stated by Hesse, Fontain, and others to give complete cure in 60 per cent. of the cases, and a mortality after the operation of 13 per cent., concludes that most of these patients have not been under observation for sufficient length of time, and suggests that at least four years should be allowed before claiming complete cure. The author gives notes of a characteristic case in which, under hedonal, the depressor nerve on the left side of the neck was cut, the lower half of the upper sympathetic ganglion was excised, and the branch of the descending hypoglossal divided. Soon after the operation the pain and breathlessness ceased. For more than four years the patient reported himself from time to time as perfectly healthy. This example leads the author to the belief that the operation on the cervical sympathetic is to be regarded not merely as a temporary but as a lasting benefit in cases of angina pectoris.

Therapeutics.

189. Medicinal Therapy of Duodenal or Gastric Ulcer.

J. L. ROUMAILLAC (*Journ. de Méd. de Bordeaux et du Sud-Ouest*, May 20th, 1929, p. 411) describes a medicinal treatment of duodenal or gastric ulcer, based on the discovery of what he terms "physiological duodenal regurgitation." Jarno's recent researches have shown that deficiency or arrest of duodenal regurgitation favours the production of gastro-duodenal ulceration, and he believes that the regurgitation of alkaline bile and mucus into the stomach protects the gastric mucous membrane from auto-digestion. The diminution of the percentage of cholesterin in the blood is especially due to diminution or arrest of regurgitation of bile from the duodenum into the stomach. The syndrome of hypocholesterinaemia, diminished or absent duodenal regurgitation, and of hyperacidity, is usually characteristic of chronicity of the lesions, or is a sign of recurrence of ulceration. Ox-bile has been prescribed therapentically for many centuries, but its employment in gastric or duodenal ulcer is much more modern. On account of the hypocholesterinaemia, one investigator has added to the alkaline bile a large quantity of cholic acid; he prescribed the oral administration of compressed tablets composed of desiccated ox-bile and glycocholic acid and extract of sage, of each 10 cg., with an excipient. It is stated that this preparation has given most satisfactory results. Roumaillac describes his own personal experience of this treatment, which he has found more efficacious than any other. A surgeon had diagnosed his condition as a severe gastropathy, combined with plastic periduodenitis involving the ampulla and pancreas. An operation was not advised as the general condition was very poor. Roumaillac now prescribes these tablets for dyspepsia and nausea or vomiting due to excess of fatty or highly flavoured food, or when these symptoms follow mental overexertion. Several other writers have found that they give satisfactory results in essential hyperacidity, and in gastric or duodenal ulcer. Improvement persists after discontinuance of the treatment, which renders unnecessary the prescription of severe and protracted dietetic treatment.

190. Quinidine Sulphate in Auricular Fibrillation.

L. WOLFF and P. D. WHITE (*Arch. Int. Med.*, May, 1929, p. 653) report a clinical study of the action of quinidine sulphate in 62 cases of permanent auricular fibrillation, 8 cases of permanent auricular flutter, 29 cases of paroxysmal auricular fibrillation, 2 of paroxysmal auricular flutter, and a small group of cases with paroxysmal tachycardia and premature beats. A review of a series of 75 additional cases of permanent auricular fibrillation and flutter similarly treated and recorded in 1923 is also included. (See *Epitome*, 1923, vol. i, para. 425.) The authors report that, in the series of 70 cases of permanent auricular fibrillation and flutter, normal rhythm was restored in 65.7 per cent. In 7 cases permanent auricular fibrillation in an apparently normal heart was terminated by quinidine; the authors remark that these patients are the most satisfactory to treat, the next most responsive group being that of patients with rheumatic heart disease who are under the age of 41. In the hyperthyroid group the response is somewhat better than in patients with hypertensive and arterio-sclerotic heart disease. In the case of abnormal hearts the response to quinidine treatment is surprisingly good when the fibrillation has lasted less than a month; beyond this point the duration is of little importance. In rheumatic heart disease quinidine is more effective in patients under the age of 40, but the presence of recent congestive failure reduces the probability of success. Factors contributing to failure are: insufficient quinidine dosage, intercurrent infections, and, possibly, alcoholism. The authors think that it is highly desirable to give full therapeutic doses of digitalis to all patients as a matter of routine before starting quinidine; no harm has been observed from the combined use of these two drugs. They conclude that quinidine is valuable in preventing and terminating paroxysmal auricular fibrillation, and that it is effective also in some cases of paroxysmal tachycardia and premature beats. In auricular flutter, however, digitalis is probably the more effective, and also in occasional cases of paroxysmal auricular fibrillation and paroxysmal tachycardia. Following up the cases treated in previous years has led the authors to

believe that this restored normal rhythm is permanent in a significant number of patients. Although there is no definite evidence that such normal rhythm prolongs life or reduces mortality, they think it is clearly evident that the health of the patient is promoted.

191. Malarial Therapy in General Paralysis.

J. LÉPINE, L. BOURRAT, H. CHRISTY, and E. LARRIVÉ (*Journ. de Méd. de Lyon*, June 20th, 1929, p. 397) believe that malarial therapy constitutes the surest method of obtaining remissions and practical cures in general paralysis, and record the results in 80 cases so treated. Among these there were only 9 (a little over 11 per cent.) deaths that could be ascribed to the treatment. However, greater benefit can be obtained by combining injections of a pentavalent arsenical preparation such as stovarsol or tryparsamide with the malaria inoculation. The results depend essentially on the earliness of diagnosis and treatment, which should be instituted on the appearance of the first mental troubles without waiting for the dysarthria and more marked symptoms to develop. When the disease has become established the chances of success are greatly lessened. Malarial therapy is contraindicated in certain conditions. Patients with the depressing and debilitating forms of the disease, and those in whom it develops sudden exacerbations, tolerate the treatment badly; it should also not be given to the very elderly or when there are concomitant organic affections, especially tuberculosis, diabetes, and nephritis. The aortitis so frequently encountered is not a contraindication. Alcoholic patients must be freed from this poison before beginning treatment. Various complications have been noted during the course of malarial inoculation—namely, intestinal obstruction; pleural, pericardial, and peritoneal effusions; icterus; and oedemas. In order to lessen the malarial paroxysms two injections of 0.5 gram of quinine urethane are efficacious, while an injection of 0.15 gram of novarsenobenzol will usually convert the daily into the better tolerated tertiary type. The authors believe that early treatment and its lessened duration, the reduction of the number of paroxysms to eight or ten, and greater experience of the method will result in still better success than has been reported yet.

192. Serum Treatment of Cerebro-spinal Meningitis.

E. L. BENJAMIN (*Arch. of Ped.*, April, 1929, p. 252) records four illustrative cases in children aged from 6 to 12 years, in whom there was no history of exposure to infection and the onset was sudden. He mentions that in spite of difference of opinion as regards the amount and site of injection of serum the best results are obtained by early intensive treatment combined with intravenous and intramuscular injections. In a series of nine cases seven were cured by this procedure. The prognostic value of sugar in the cerebro-spinal fluid was shown by the improvement which occurred on its reappearance. Benjamin urges that cistern puncture should be resorted to more frequently, as it is not attended with any great danger to the patient when properly performed.

Disease in Childhood.

193. Fractures of the Femur in Children.

H. E. CONWELL (*Journ. of Bone and Joint Surg.*, July, 1929, p. 593) reports the results of treating 85 cases of acute fractures of the shaft of the femur in children. The main forms of treatment are: (1) plaster cast; (2) plaster cast and extension (adhesive, callipers, or Steinmann pin); and (3) suspension and extension. Good results have been obtained with each form of treatment, but the last is the most popular, and has several variations, such as Buck's extension; skeletal traction in the horizontal or perpendicular position; suspension and extension of one or both thighs in a perpendicular elevation with adhesive traction to the skin; extension of one or both thighs in a horizontal or perpendicular position with the help of Thomas or Hodgen splints, or the Bradford frame. Treatment by open reduction is usually unnecessary, and should be the last resort. Better results of plaster cast treatment are obtained in very young children, while in older children the use of plaster casts with extension are more successful; a summary of the cases shows, however, that up to the age of 10 or 11 the best results of all ensue in those treated by suspension and extension. Physical and radiological examinations should first be made and immediate reduction with the aid of a fluoroscope be done, unnecessary manipulation being avoided. Frequent applications of physiotherapy treatment are recommended to help the conservation of the muscle and the motion of the joints, thus preventing grave deformities and permanent disabilities. Good alignment is of the first importance—then bone approximation. Compensatory lengthening and correction of poor alignment does occur in children under the age of 8. The suspension and extension method is the most comfortable dressing; it facilitates daily examinations, frequent checking with x rays, dressings in compound wounds, and makes easy the application of radiant heat, hot baths, and active and passive motion. These measures shorten convalescence and give better functional results.

194. Streptococcal Septicaemia in Infants.

FONTAYNE, MILLET, and VERHOOGEN (*Journ. de Méd. de Paris*, July 4th, 1929, p. 572), who record two fatal cases, state that streptococcal septicaemia in infants is a formidable and fairly frequent occurrence, the clinical diagnosis of which is not easy, especially at the onset and in certain very acute forms. As in the septicaemias of the adult a blood culture should be taken under favourable conditions. In infants this is only possible by puncture of the superior longitudinal sinus through the anterior fontanelle. The authors' first patient was a female infant, aged 5 months, who developed a streptococcal infection of a septico-pyaemic type which lasted for three months. During this period numerous streptococcal foci appeared, first in the cervical lymphatic glands, then in the skin and subcutaneous tissue, and lastly in the form of broncho-pneumonia, pulmonary abscesses, and ulcerative endocarditis. The second case occurred in a male infant, aged 4 weeks, in whom the disease lasted only six days, and was characterized by streptococcal infection of the skin, subcutaneous tissue, lungs, and meninges. In neither instance could the portal of entry of infection be discovered.

195. Diarrhoea and Vomiting in Infants.

M. MAIZETS and CATHERINE B. MCARTHUR (*Quart. Journ. Med.*, July, 1929, p. 581) investigated the significance of acidaemia and alkalaemia in the diarrhoea and vomiting of infants during an epidemic of acute gastro-enteritis by determining before treatment commenced the degree of acidosis and its response to sodium bicarbonate. The *p*H and bicarbonate content of the plasma were measured as well as, in many cases, the chloride, urea, and phosphate content. In order to ascertain whether the presence or absence of acidosis could be inferred from the examination of the urine its *p*H, titratable acidity, the ammonia-combined acid, and urea were estimated, as well as the presence or absence of acetone bodies and the content of chloride and phosphate. An acidaemia was found to be present in most cases of infantile diarrhoea and vomiting, but there may be an alkalaemia in some in which the reduction in the osmotic pressure of the blood may be so great that a retention of base occurs leading to the excretion of an acid urine. Acidosis is probably absent if the urine is neutral or alkaline, or the ammonia coefficient is below 8 per cent., or the ammonia-combined acid is less than twice as great as the titratable acid; in such circumstances if the chloride is persistently absent from urines of average concentration extra sodium chloride should be administered, while it is probably unsafe to give alkali. Acidosis is not necessarily present if the urine is acid, the ammonia coefficient is above 8 per cent., and the ratio of ammonia-combined acid to titratable acid is greater than 2.5. The prognosis of a case cannot be gauged from the level of the plasma bicarbonate, since it was found that certain patients with great depletion of the alkali reserve of the blood rapidly improved, while in some of the very severe cases the plasma bicarbonate was only moderately lowered.

196. Intestinal Toxaemic Deafness in Children.

M. YEARSLEY (*Brit. Journ. Child. Dis.*, April-June, 1929, p. 116), who records three illustrative cases in boys, aged from 7 to 8½ years, states that there are certain cases of deafness in children in which the functional reactions point to an internal ear condition. Enlarged tonsils and adenoids may be present, but their removal does no good. Inspired by McDonagh's recent work on chronic intestinal intoxication Yearsley has repeatedly found that there are catarrhal conditions of the upper air passages, with and without accompanying middle-ear complications, which refuse to clear up until the primary intestinal toxaemia has been treated by diet, colon lavage, and vaccines in place of the present perfunctory prescriptions of one or more proprietary purgatives. He also maintains that oto-sclerosis is primarily a toxaemia affecting the cortical cells of the auditory area, the changes in the labyrinthine capsule being probably of a trophic nature. In each of the six cases of oto-sclerosis which he found among 1,521 cases of educational deafness, chronic intestinal intoxication was present, as it was also in their mothers. During the last three years he has found septic tonsils and carious teeth so often associated with chronic intestinal intoxication that he has come to the conclusion that the latter is the primary focus, and the first two merely secondary.

Obstetrics and Gynaecology.

197. Kraurosis Vulvae.

W. P. GRAVES and G. VAN S. SMITH (*Journ. Amer. Med. Assoc.*, April, 1929, p. 1244) adopt the term "kraurosis vulvae" as a name to comprise the changes which may occur at the vulva and which tend towards malignancy. In an account of the history of this condition, the authors mention some of the earlier cases recorded. Breisky, who was the first to apply the name kraurosis, on account of the tissue retraction, also described the condition now termed leucoplakia, but looked upon it as a form of kraurosis. The relation of kraurosis to leucoplakia is discussed by the present authors, who remark that opinion is divided as to whether the diseases are separate entities or phases of the one process. Berkeley and Bonney regard them as distinct diseases; Jayle holds the view that leucoplakia is the secondary change in the primary disease, kraurosis; while Syàsz looks on kraurosis as the end-result of leucoplakia. The authors believe the two conditions to be stages of the one process. Accordingly they recommend that kraurosis should be the generic title of the whole disease, which, they say, may begin as an irritative vulvitis, marked by pruritus, and passing in the course of time to the superficial epidermal changes characteristic of leucoplakia, while the deeper changes result in the retraction typical of kraurosis. G. van S. Smith has formed the opinion that the only real histological difference between leucoplakia and kraurosis is a greater activity of the squamous epithelial layer in the former. He believes that leucoplakia may precede or follow kraurosis; and that carcinoma vulvae is most commonly preceded by "leucokraurotic" change. He thinks, moreover, that there is a greater tendency for carcinoma to develop on a leucoplakic base than on a kraurotic one. In considering the treatment, pruritus in the early stages may be dealt with according to its cause by establishing proper genital drainage, by warning against sexual abuse, and by the application of hydrous wool fat. When the changes of kraurosis or leucoplakia are present, removal of the diseased area by a partial or complete vulvectomy is required. Treatment by irradiation is condemned.

198. Suprarenal Tissue in the Broad Ligament.

R. PETIT (*La Gynécologie*, May, 1929, p. 257) discusses the occurrence of metastatic deposits of suprarenal tissue in the broad ligament. Embryological development explains the facility with which isolated portions of suprarenal tissue may be found near the genital organs. Petit quotes the figures of R. May, who discovered ten such instances in forty necropsies. Since it is impossible to diagnose these small tumours clinically the author has made a practice of carefully searching for them in the course of laparotomies; he found five in 175 cases, and adds that they generally occur on the posterior surface of the broad ligament at a variable distance between the horn of the uterus and the ovary. They are about as large as peas, but one had become the size of a large cherry. They are rounded, firm, and covered by peritoneum. The colour is particularly characteristic, being a sulphur yellow. Microscopically these islets of tissue show the typical structure of the suprarenal gland. It is known that this structure is capable of becoming malignant; the author therefore considers it advisable to examine the broad ligament in all laparotomies and to extirpate any small tumour which may be found. Discussing the question whether these isolated patches of suprarenal tissue might serve any useful purpose the author states that in his own cases no ill effects followed their removal, even after a long time.

199. Radium Treatment of Fibroids.

F. A. CLELAND (*Amer. Journ. Obstet. and Gynecol.*, April, 1929, p. 503) records his observations on 200 cases treated by radium, 98 of which were diagnosed as fibrosis uteri and the rest as fibroids. Two-thirds of the patients were between 38 and 50 years of age, and only 15 of the fibrosis uteri cases and 13 of the others were under 38. Of all cases which required treatment, 25 per cent. were fibrosis uteri cases, for which radium is the safest and most economical treatment, and 75 per cent. were fibroids; of these, only about one-third were suitable for radiation, surgical treatment being required in the rest. Radium is contraindicated in the following cases: (1) fibroids larger in size than a three and a half months' pregnant uterus; (2) fibroids causing pressure symptoms, such as frequent micturition, difficulty in defaecation, or unilateral oedema of the leg; (3) adnexal disease or ovarian tumour; (4) symptoms suggesting degeneration of the fibroid; (5) subperitoneal fibroids; (6) in cases where the diagnosis is uncertain; (7) in young women where myomectomy is preferable to radiation; and (8) the coexistence of another pathological abdominal condition requiring treatment.

Pathology.

200. The Complement-fixation Reaction in Rabies.

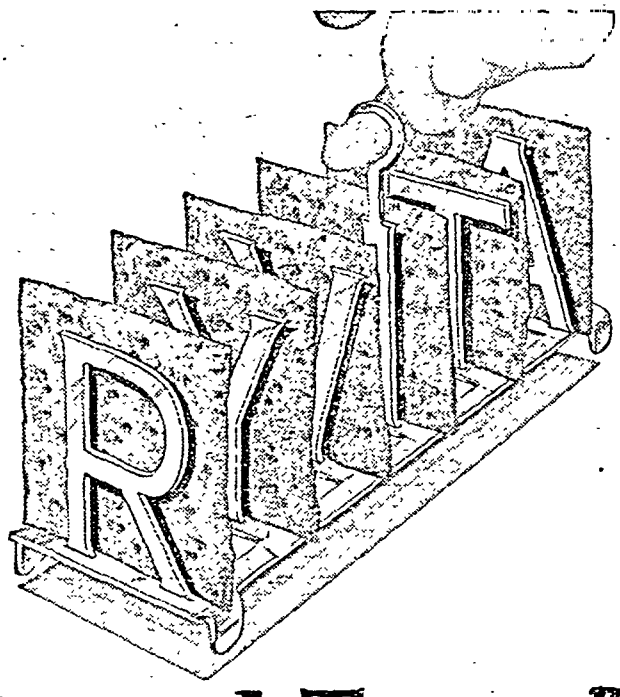
A. C. MARIE and A. URBAIN (*C. R. Soc. de Biologie*, June 21st, 1929, p. 561) have examined the serum of a rabbit immunized against rabies for the presence of sensitizing antibodies. The serum, after filtration through a Chamberland L3 candle, was found to neutralize ten times its volume of a 1 in 100 suspension of fixed virus, whereas normal serum was unable to neutralize even one volume. Precipitins were demonstrated by mixing the serum with a 1 in 100 suspension of virus, which had been filtered through paper. To show the presence of complement-fixing antibodies two antigens were used. The first, a cocto-antigen, was prepared by grinding up a rabic brain in ten times its volume of saline, heating to 100° C. for half an hour, centrifuging, and removing the supernatant fluid; the second was prepared by grinding up the finely pulverized brain in nine volumes of saline, leaving overnight in the ice-chest, and pipetting off the supernatant fluid. Using the cocto-antigen it was found that, though 10 units of complement were fixed in the presence of a rabic serum from an animal immunized against rabies, the same result was obtained with a suspension of a normal or a herpetic brain. On the other hand, using the unheated antigen, a specific reaction was obtained; the rabic brain in the presence of an antirabic serum fixed 150 units, and in the presence of normal rabbit serum only 15 units; a herpetic or a normal brain in the presence of an antirabic serum fixed 30 units, and in the presence of a normal serum 15 units. It would therefore appear that an antirabic serum contains neutralizing antibodies, precipitins, and complement-fixing antibodies—the latter being demonstrable by a fresh but not by a heated antigen.

201. The Value of Vegetable Extracts in Culture Media.

L. THOMPSON (*Journ. Bact.*, May, 1929, p. 379) prepared aqueous extracts of potato, carrot, radish, spinach, and ox heart. When freshly prepared the various extracts seemed to be about equal in growth-promoting power, but certain ones, especially the spinach and ox heart extracts, turned acid on standing, and a precipitate was formed, after which their value was greatly decreased. Similarly, autoclaving at 20 lb. pressure for 15 minutes precipitated the protein in some of the extracts, and correspondingly diminished their value. The most satisfactory extract was found to be that from potatoes. The addition of as little as 0.01 c.cm. of this extract to 6 c.cm. of plain broth enabled the growth of streptococci to occur. Both the protein and the non-protein nitrogen fractions served to stimulate growth, but not in so marked a degree as the whole extract. No correlation was found between the amount of reducing sugar in the extracts and their power to stimulate growth. Thus extract of ox heart, which contained only 0.04 per cent. of sugar, was slightly superior to carrot extract, which contained more than twenty times that amount. It would appear, therefore, that the substance responsible for promoting growth is associated with the nitrogen fraction of the extract. In the author's opinion it is probably a food substance proper rather than an accessory food substance or vitamin.

202. The Nature of Bacterial Resistance to the Bacteriophage.

F. M. BURNET (*Journ. Path. and Bact.*, July, 1929, p. 349) prepared from the normal smooth and rough forms of *Bact. sanguinarium* variants resistant to one phage type. Four strains were then available: smooth-susceptible, smooth-resistant, rough-susceptible, and rough-resistant. Immune serums were prepared from each of these strains by inoculating rabbits. Cross-absorption experiments showed that the two smooth strains were identical serologically, and that the two rough strains likewise were indistinguishable. The power of the four strains to absorb phage was then tested. Three strains of phage were used: one active against the smooth parent strain, one active against the rough parent strain, and one active against both smooth and rough parent strains. The results showed that while the parent strains were able to absorb the particular strain of phage to which they were sensitive, the variant resistant strains were unable to do so. It would appear from these experiments (1) that no antigenic difference can be detected between the parent susceptible form and the variant resistant form, and (2) that with the development of resistance the ability to absorb the phage involved is lost. Burnet, in previous papers, has assumed that the element in the bacterium which is capable of absorbing phage is identical with the heat-stable somatic O antigen. In view of the results recorded in the present paper this assumption must either be abandoned or modified by the further assumption that changes can be detected by phage absorption which cannot be detected by agglutinin absorption.



Toast *and* Toast Racks superseded

The "RYVITA RACK" has displaced the old-time toast rack

Every day, more and more people are discovering how much more delicious, how much better than toast is "Ryvita Crispbread," the wonderful daily bread of Sweden.

"Ryvita" is made of rye—and nothing but rye—the only cereal from which this the true Crispbread can be made. The first people in this country to eat it were those most highly qualified to judge food values—doctors, dentists, and dietetic experts. "Ryvita" reached the multitude by way of the specialist, thus—despite envious imitators—establishing here "The Ryvita Crispbread Habit."

Eaten as your Daily Bread—"Ryvita," the Veritable Bread of Life, helps to make indigestion, constipation, malnutrition, and obesity unknown. Yet . . . so unique is this wonderful bread, that it is practically impossible, even when dieting, to eat too much of it.

Try "Ryvita" with butter and marmalade. Notice how it sustains without cloying . . . how it gives you an exhilarating sensation of well-being and clear-headedness . . . how you work better, play better, and feel better on "Ryvita."

You will then understand why the old toast rack is now the "Ryvita" rack.

Send a postcard for generous FREE Sample to the Ryvita Company, 418, Ryvita House, 56, Southwark Street, London, S.E.1. Sold by all good grocers and stores at 1/6 per (40-50 slice) 1-lb. carton; ½-lb., 10d.

Makes you fit— **RYVITA CRISPBREAD** keeps you slim

SULPHAQUA

LARGELY AND SUCCESSFULLY PRESCRIBED IN

Skin Diseases, Rheumatism, Gout, Neurasthenic : : Conditions in Arthritic Subjects, Etc. : :

And as a valuable addition to the Inunction TREATMENT OF SYPHILIS with Mercury.

Employed in BATH and TOILET BASIN.

Possesses powerful Antiseptic, Antiparasitic, and Antalgic properties. Relieves intense Itching and Pain, is WITHOUT OBJECTIONABLE ODOUR, and does not blacken the bath enamel. Recommended for the Skin and Hair. Especially useful in the treatment of Acne and Seborrhœa of the Scalp. Largely used in dermatological practice.

SULPHAQUA SOAP.

In Boxes of ½-doz. and 1-doz. BATH CHARGES, 2-doz. TOILET CHARGES, and ½-doz. SOAP TABLETS.

Samples and Literature on Request. Advertised only to the Profession.

THE S. P. CHARGES CO., Manufacturing Chemists, St. Helens, Lancs.

"SULPHAQUA" is stocked by the leading Wholesale Houses in Canada, Australia, New Zealand, South Africa, India, U.S.A.

PURE HÆMOGLOBIN

(Lecithin, Albumen, Calcium Lactate and Soluble Silicic Acid)

IN GRANULE FORM

SICCOPAN is a new treatment for anæmia, chlorosis and general physical weakness. It takes an intermediate place between drugs and foodstuffs, and possesses the characteristic valuable properties of both. It is especially suited for the support of the convalescent patient in his striving towards recovery.

Siccopan forms a valuable addition to the physician's therapeutic armoury.

Samples and literature to medical profession on request to Sole Agents for United Kingdom and Colonies:

need no longer be lost through Tyre Trouble

Tyres can now be reinforced by means of the Stronghold Tyre Liner which effectively prevents nails, flints, and other sharp bodies, which penetrate the outer cover, from reaching the tube. Punctures and blowouts are eliminated even in the case of a badly worn or cut tyre, and the liners add fully 5,000 miles to the life of any tyre. While being necessarily of particularly tough construction these liners have a resiliency equal to that of the tyre itself and do not reduce the speed or comfort in any way. Made to the exact size and shape of the particular tyre for which they are required they slip into place as easily as the inner tube, and vulcanize themselves securely to the cover after a few miles run on the road.

TEST OFFER.

Equip Your Chauffeur at GAMAGES

Thousands of Britain's Smartest Chauffeurs wear Gamage Liveries. It is because wise employers know that at Gamages they obtain the finest quality cloths and specialised Livery Tailoring. Here are two typical examples of the splendid values Gamages offer.

The Gamage "CAVENDISH" OVERCOAT

Made from hard-wearing Blue Melton Cloths and lined Tweed throughout. Overcoats are made in two styles—(1) as (illustrated); (2) button to neck. Ready for service in all fittings. 95/- 115/6 130/- **72/6**

The Gamage "BROOKLANDS" SUIT

Complete Trouser Suit. Double-breasted Jacket, Vest and Trousers, made from a good weight Navy Blue Ribbed Serge. The Gamage "Brooklands" indicates neatness combined with style, and can be purchased Ready for Service. 95/- 115/6 **84/-**

GAMAGES, HOLBORN, LONDON, E.C.1

The Gamage "Cavendish" Overcoat

WILL YOU ACCEPT ¼lb. GRATIS?

In order that Doctors all over the country may test the tea their colleagues have so generously recommended, we will send ¼-lb. free to any medical man who will write for it. This offer applies solely to members of the Medical Profession.

DOCTOR'S CHINA TEA

FOR many years Doctors have recommended our China Tea to Invalids and Dyspeptics when ordinary tea was out of the question. The Medical Press, too, has commented frequently upon the merits of this particular blend—and so we call it DOCTOR'S China Tea.

It is a perfect blend of the finest China leaf with all excess tannin eliminated.

Invalids and dyspeptics can drink it with no ill effects.

Private. Fitting Rooms.

System 11.

BELT FOR GENERAL SUPPORT.

Pre-eminently useful after confinement, affording the most effectual support to the internal organs, preventing pressure on the fundus of the womb.

System 11 should be used in all cases where the abdominal muscles need support. It also invariably gives good results in cases of enteroptosis, gastroptosis, and all similar troubles.

THE POSTAL ACCOUNT

It is often supposed that to live a long way from the nearest branch of a bank, or to be constantly unable to go to the bank in person, is a handicap to the enjoyment of the full advantages which, it is admitted, a banking account offers. Perhaps it is assumed that to conduct an account by post involves 'more letter writing', or is costly, or is not welcomed by the Bank. It is the aim of the Westminster Bank to dispel such misconceptions by a leaflet entitled *The Postal Account*, which explains the convenience of the method, and offers some clear suggestions.

The Secretary of the Bank will be pleased to send a copy on application

ST. ANDREW'S HOSPITAL
FOR MENTAL DISORDERS,
NORTHAMPTON

FOR THE UPPER AND MIDDLE CLASSES ONLY.

President: THE MOST HON. THE MARQUESS OF EXETER, C.M.G., A.D.C.

Medical Superintendent: DANIEL F. RAMBAUT, M.A., M.D.

This registered Hospital is situated in 120 acres of park and pleasure grounds. Voluntary Boarders, persons suffering from incipient nervous and mental disorders, as well as certified patients of both sexes, are received for treatment. Careful clinical, biochemical, bacteriological, and pathological examinations. Private rooms with special nurses, male or female, in the Hospital or in one of the numerous villas in the grounds of the various branches can be provided.

WANTAGE HOUSE.

This is a Reception Hospital in detached grounds, with a separate entrance, to which patients and voluntary boarders can be admitted. It is equipped with all the apparatus for the most *modern* treatment of Mental and Nervous Disorders. It contains special departments for hydrotherapy by various methods, including Turkish and Russian baths, the prolonged immersion bath, Vichy Douche, Scotch Douche, Electrical baths, Plombières treatment, etc. There is an Operating Theatre, a Dental Surgery, an X-ray Room, an Ultra-violet Apparatus, and a Department for Diathermy and High Frequency treatment. It also contains Laboratories for biochemical, bacteriological, and pathological research.

MOULTON PARK.

Two miles from the Main Hospital there are several branch establishments and villas situated in a park and farm of 650 acres. Milk, meat, fruit, and vegetables are supplied to the Hospital from the farm, gardens, and orchards of Moulton Park. Occupation therapy is a feature of this branch, and patients are given every facility for occupying themselves in farming, gardening, and fruit-growing.

BRYN-Y-NEUADD HALL.

The Seaside house of St. Andrew's Hospital is beautifully situated in a Park of 330 acres, at Llanfairfechan, amidst the finest scenery in North Wales. On the North-West side of the Estate a mile of sea coast forms the boundary. Voluntary Boarders or Patients may visit this branch for a short seaside change or for longer periods. The Hospital has its own private bathing house on the seashore. There is trout-fishing in the park.

At all the branches of the Hospital there are cricket grounds, football and hockey grounds, lawn tennis courts (grass and hard courts), croquet grounds, *golf courses, and bowling greens.* Ladies and gentlemen have their own gardens, and facilities are provided for handicrafts, such as carpentry, etc.

For *terms and further particulars apply to the Medical Superintendent (Telephone No. 56.* Northampton), who can be seen in London by appointment.

The Trustees offer Scholarships under the conditions of the Dickinson Trust for part or *whole-time research work* to promote medical knowledge

The Scholarships are of the value of £75 or more per annum and are tenable for one year.

The Scholarships are open to Graduates of a University, who have received their full course of instruction in Medicine, Surgery, and Pathology at the University of Manchester and the Manchester Royal Infirmary. The scholars shall undertake and carry out some special research work, the nature of which they shall suggest but which must receive the approval of the Trustees.

For further information apply to the undersigned to whom six copies of application must *be sent not later than* September 28th.

Manchester Royal Infirmary. FRANK G. HAZELL, Secretary to the Trustees.

September 2nd, 1929.

General Hospital, Nottingham

A HOUSE PHYSICIAN is required at the above Institution. Candidates are desired to make application at once stating age, qualifications, and experience, with copies of testimonials, to the undersigned. *The appointment* is for six months. Salary at the rate of £150 a year, with board, residence, and laundry.

PETER M. MACCOLL, House Governor & *Secretary.*

COLONIAL MEDICAL SERVICES.

VACANCIES exist at present for MEDICAL OFFICERS in:—

(a) West African Medical Staff.
(b) The Malayan Medical Service.
(c) The East African Medical Service.
(d) The Northern Rhodesian Medical Service.

QUALIFICATIONS.

Applicants must be British subjects of European parentage and between 22 and 35 years of age. They must possess a double qualification and be on the British Medical Register. Preference will be given to candidates who have held hospital or public health appointments, or who have special knowledge of anæsthetics, radiology, surgery, medicine, ophthalmology, gynæcology and midwifery, diseases of the ear, nose, and throat, venereal diseases, etc.

COURSES OF STUDY.

Selected candidates will normally be required to take a special course of study in tropical medicine and hygiene, commencing on September 30th, either at the London School of Hygiene and Tropical Medicine or at the Liverpool School of Tropical Medicine, or at the University of Edinburgh, before taking up their appointments. Tuition fees will be paid and an allowance granted by Government subject to certain conditions. Completed forms of application must, therefore, reach the Private Secretary (Appointments), Colonial Office, 2, Richmond Terrace, Whitehall, London, S.W.1, from whom further particulars and forms of application may be obtained, not later than September 16th.

One or two selected candidates may be required to proceed overseas without attending a preliminary course of study.

GOVERNMENT OF IRAQ.

VACANCY for a MEDICAL OFFICER.

A vacancy at present exists for a Medical Officer in Iraq.

Qualifications.	Candidates, who should be British subjects of pure European origin, must be Fellows of one of the Royal Colleges of Surgeons, and preferably have special knowledge of gynæcology and anatomy.
Salary.	Rs.1,500/- per mensem, rising by annual increments of Rs.75/- per mensem to Rs.1,800/- per mensem, and thereafter by annual increments of Rs.100/- per mensem to Rs.2,300/- per mensem. (One rupee is equivalent to 1s 6d. sterling).
Terms of appointment.	The appointment will be on agreement for 5 years, the first year being probationary. The post is non-pensionable, but the selected officer contributes one month's salary and Government two months' salary each year towards a Provident Fund. At the end of his service the officer receives the accumulated sum, together with accrued interest.
Private Practice.	Consulting practice will be allowed but not private practice.
Passages.	Subject to the usual conditions, free first-class passages will be granted on appointment, and on termination of appointment. Free passages on leave from and to Iraq are provided once during the period of contract.
Leave.	Leave is granted at the rate of one day's leave for every five days of effective service in Iraq.

Further particulars and forms of application may be obtained, on application in writing, from the Private Secretary (Appointments), Colonial Office, 2, Richmond Terrace, Whitehall, London, S.W.1.

COMPLETED APPLICATIONS MUST BE RECEIVED BY THE PRIVATE SECRETARY NOT LATER THAN WEDNESDAY, THE 18th OF SEPTEMBER, 1929

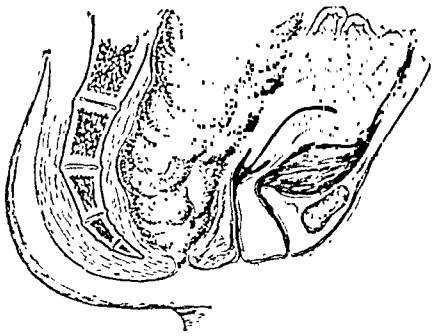
The Menace of the Overloaded Bowel



always present, easily becomes serious in women. It causes interference with the pelvic circulation and tends to produce congestion of the uterus, not infrequently followed by functional disorders, producing dysmenorrhœa, menorrhagia, and even inflammatory conditions.

AGAROL Brand Compound gives relief and frequently permanently restores the functional activity of the colon. One tablespoonful before retiring, gradually decreased as improvement takes place, is especially well adapted for the treatment of constipation in women, because of the gentle action of Agarol Brand Compound and absence of irritation from its use.

A liberal trial quantity at the disposal of physicians.

Agarol Brand Compound is the *original* Mineral Oil—Agar-Agar Emulsion (with Phenolphthalein) and has these advantages:
Perfect emulsification; stability; pleasant taste without artificial flavouring; free from sugar, alkalies and alcohol; no oil leakage; no griping or pain; no nausea; not habit forming.

ESSENCE of RENNET

CONCENTRATED (BENGER).

(Curdling Fluid)

Originally prepared at the request of a prominent physician, this highly concentrated essence is of especial value in Infant and Invalid Feeding. As it is concentrated it is much quicker in its effect than most other preparations of Rennet. Whey prepared with Benger's Essence of Rennet is of the greatest value in the treatment of diarrhœa, vomiting, etc.; it can be employed with confidence and will yield good results. Junket can be made more quickly and at a lower cost by using Benger's Essence of Rennet than by any other method.

In 1/- and 1/9 bottles.
Larger sizes for hospitals, etc., use.

LIQUOR PEPTICUS

(BENGER).

"A digestive agent of extraordinary power."
Sir William Roberts, M.D., F.R.S.

Benger's Liquor Pepticus, is a concentrated and highly active fluid pepsin in acid solution which acts particularly upon meat, eggs and other proteid foods.

The best results from the use of Liquor Pepticus are obtained when it is prescribed alone. Should the prescriber wish to combine medicaments of a tonic nature, it will be recollected that those which are free from astringency and alkalinity should be selected.

In 4, 8 and 16-oz. bottles.
Prices: 3/6, 6/6 and 12/6.

REGD. TRADE MARK.

The Product of Unique Experience

PARKE, DAVIS & Co. introduced Adrenalin to the medical profession in 1901. During the twenty-eight years that have elapsed, they have manufactured it continuously, and their long experience has convinced them that natural Adrenalin possesses many advantages over the synthetic product.

Adrenalin (P., D. & Co.)—the original and well-tried preparation—is extracted from the medullary portion of selected adrenal glands. The isolated substance is then standardised by both physiological and chemical methods to secure full activity of the finished preparations.

Medical men can make sure of obtaining an Adrenalin that is potent, uniform in action, and reliable by specifying "P., D. & Co.".

Full particulars of Adrenalin (P., D. & Co.) and its uses in medicine will be supplied on request. Adrenalin Chloride Solution, P., D. & Co., is supplied in bottles and ampoules. Hypodermic Tablets, Inhalant, Lozenges, Suppositories, Ointments, etc., and Adrephine (Adrenalin-Ephedrine Compound) are also available.

SCULPTURED FIGURE BELONGING TO THE TIME OF THE EARLIEST INDIAN EMPIRE.—For at least 1000 years before the time which we can illustrate by actual archæological monuments of contemporary date, there had existed in India a well-developed and prosperous civilisation. This we know from the vast literature represented by the Vedas, the great epic poems, the Mahabharata and the Ramayana, books of law and other writings. From these, we learn that, in building and consolidating the empire, war was looked upon as a necessity, though, later, as we know, Asoka renounced war. We can recover from ancient Indian literature many ideals which are often claimed as modern; for instance, the ideal of kingship; a king should "first subdue himself, and then seek to subdue his foes. How should a king who has not been able to conquer his own self be able to conquer his foes?" In his coronation oath the king swore to "consider always as God whatever is law and whatever is in accordance with ethics, and whatever is not opposed to policy; I will act according to that and will never act arbitrarily." Not literature alone, but the developed state of the arts, as evidenced by figures such as the one here reproduced, certifies to a long history of civilisation and of settled government in the land to which it belongs.

The Issue of the BRITISH MEDICAL JOURNAL is this week 39,000 copies.

New Books—New Editions

Granger's Physical Therapeutic Technique

NEW

One of the outstanding features of the book is the "Index of Diseases." This section of 140 pages lists diseases and conditions alphabetically and under each gives the physical therapeutic method or methods likely to be most beneficial. Indications and frequency of the treatment, the technique, dosage, etc., are given and there are numerous illustrations to demonstrate the instruction of the text.

Octavo volume of 417 pages, illustrated. By FRANK B. GRANGER, M.D., late Physician-in-Chief for Physical Therapy at the Boston City Hospital. Cloth, 30s. net

Mellish-Wilson's Writing of Medical Papers

THIRD EDITION

This book will aid medical writers to prepare their manuscripts in order to convey information with brevity, accuracy, and clearness. It includes chapters on words in good usage, italics, punctuation, pitfalls in diction, case histories, chapter, paragraph and sentence, references, revision, manuscripts, marking corrections, etc.

By MAUD H. MELLISH-WILSON, Editor of The Mayo Clinic Publications. 12mo of 184 pages. Cloth, 7s. 6d. net

Willius' Electrocardiograms

A MAYO CLINIC MONOGRAPH

This is a brand new book—a new volume in the "Mayo Clinic Monographs." The entire book is devoted to the *reading*, to the *interpretation* of the records themselves and to the clinical significance of the findings. The 368 illustrations are clearly explained by detailed legends which in themselves comprise a complete text and frequently give the required help without reference to the text.

Quarto volume of 219 pages, with 368 electrocardiograms. By FREDERICK A. WILLIUS, B.S., M.D., M.S. in Medicine, Section on Cardiology, The Mayo Clinic, Rochester, Minn.; and Associate Professor of Medicine, The Mayo Foundation, University of Minnesota. Cloth, 36s. net

Gleason on Nose, Throat and Ear

SIXTH EDITION

All modern and proved methods of diagnosis and treatment are reflected in this *Sixth Edition*. Dr. Gleason revised the book thoroughly—so thoroughly, in fact, that it was necessary to reset the book. He added valuable new methods of diagnosis and treatment, new instruments, new operations, new and improved formulas. Many new illustrations were inserted.

By E. B. GLEASON, M.D., LL.D., Professor of Otology, Medico-Chirurgical College Graduate School of Medicine, University of Pennsylvania. 12mo of 617 pages, illustrated. Cloth, 21s. net

McKendree's Neurological Examination

Here is a book aimed to help practitioners and students to avoid mistakes in diagnosis. It outlines a form of examination and history-taking in logical step-by-step method. Tests are detailed. The author makes clear *why* the test is applied and tells how to correlate abnormal findings with the expressed symptoms.

12mo of 289 pages, illustrated. By CHARLES A. MCKENDREE, M.D., Associate, Department of Neurology, College of Physicians and Surgeons, Columbia University. Cloth, 15s. net

Wechsler on the Neuroses

NEW

This book is unusually rich in diagnostic helps. Psychiatric facts are emphasized in a chapter on differential diagnosis. Attention is drawn sharply to the organic, neurologic and other medical conditions that might lead to diagnostic errors. There is a concise chapter on taking a psychiatric and neurologic history and on making a mental examination. Full technique is given for making tests.

Octavo of 330 pages. By ISRAEL S. WECHSLER, M.D., Associate Professor of Clinical Neurology, Columbia University, New York City. Cloth, 18s. net

W. B. SAUNDERS COMPANY Ltd., 9, Henrietta Street, LONDON, W.C.2

AN INDEX OF SYMPTOMATOLOGY

By Twenty-six Distinguished Contributors.

Edited by

H. LETHEBY TIDY, M.A., M.D.Oxon., F.R.C.P.Lond.,
Asst. Phys., St. Thomas's Hospital; Con. Phys., Royal Northern Hosp.

This book is intended to provide an account of the symptomatology of disease. The general object has been to give a clear and reasonably full description of the clinical manifestations of each disease, without dwelling unduly on minor complications and variations.

BRITISH MEDICAL JOURNAL:—"Should help considerably in the solution of difficult diagnostic problems. The articles, which cover all branches of medicine, surgery, gynæcology, and the specialties, are tersely written and well up to date."

Bristol: JOHN WRIGHT & SONS Ltd. [Illustrated Catalogue free.] London: SIMPKIN MARSHALL Ltd.

VOL. I (Nineteenth Edition). 27s. 6d. net; postage 6d.
VOL. II (Eighteenth Edition). 20s. net; postage 6d.
The Complete Work in Two Vols., 47s. 6d. net; postage free.

English Doctors through nine centuries

THE HARLEY STREET CALENDAR

By H. H. BASHFORD. *7/6 net.*

In this volume—the only modern work, we believe, of its kind—Dr. Bashford has brought together, in a series of very human and intimate character studies, eleven of the most typical English doctors since the Norman conquest.

Ranging from John of Gaddesden, mentioned in Chaucer's *Canterbury Tales*, to Lord Lister, and including such diverse characters as the Puritan soldier Sydenham and the prosperous Hans Sloane, the founder of the British Museum. Dr. Bashford has been able to collect many new and fascinating details, and the whole volume gives an absorbing, if incidental, picture of the progress of English Medicine during that period. It should, therefore, appeal not only to the many thousand readers of *The Corner of Harley Street*, but to everybody—medical and otherwise—who can be interested in an extremely varied and human company.

By the same Author:

PRICE complete, as illustrated, for use on Alternating Current, including all Accessories £350

Ditto, Apparatus for use on Direct Current £410

The outfit can be supplied with Metalix X-Ray tube instead of Coolidge X-Ray tube at an additional charge of £10.

SEND FOR DESCRIPTIVE CATALOGUE No. B10.

Now available for every Hospital.

The acme of Simplicity.

The NINETY-THIRTY **X-RAY APPARATUS**

Certified by NATIONAL PHYSICAL LABORATORIES as complying with RECOMMENDATIONS OF THE X-RAY COMMITTEE ON PROTECTION.

The power of the apparatus here shown is 90 kilo-volts at 30 milliamperes and is therefore capable of meeting the requirements of any hospital for diagnostic radiography and fluoroscopy.

The floor space occupied by the complete installation is only 9 ft. × 2 ft. and is therefore suitable for any X-ray room.

The operation of the outfit is so simple that any doctor can obtain radiograms of first-class quality even though he may have had no previous experience. The difficulties associated with X-ray work in the past are now entirely overcome by a device known as the "Automatic Technique Director" which indicates the exact setting of the controls for radiographing any part of the body. The outfit includes a full set of accessories, dark room equipment, etc., and thus COMPRISES A COMPLETE INSTALLATION.

Immediate delivery from stock.

UNVEILING WINDOWS TO HEALTH

A New Power in the Hands of Doctors

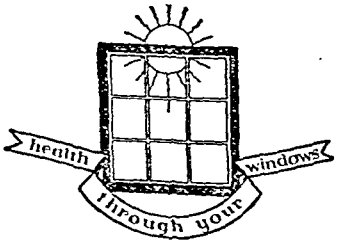
Every window of ordinary glass cuts off some room from the ultra-violet rays of daylight. Every doctor has the power to change the condition of hundreds of homes by recommending the admission of natural ultra-violet radiation through windows of "Vita" Glass.

All windows that receive direct daylight can be made, by fitting them with "Vita" Glass, into permanent inlets for health all the year round, whether they are in a town house or a country house.

The recommendation of "Vita" Glass as an enduring health measure can often prove a valuable supplement to the treatment already prescribed by medical practitioners, especially in cases that have reached the convalescent stage after a long and weakening illness. Nor need the recommendation involve great expenditure on the part of the patient, for to-day the cost of installing "Vita" Glass is moderate. For an average-sized window in a modern house, the "Vita" sheet glass costs about 38/-, plus the cost of fixing.

Invented by British science, "Vita" Glass is the only glass of its type produced by British Industry. Write for full information and prices from: THE "VITA" GLASS MARKETING BOARD, 9 Aldwych House, London, W.C.2.

"Vita" Glass is obtainable from local Glass Merchants, Painters, Glaziers or Builders.



"Vita" is the registered Trade Mark of Pilkington Brothers, Limited, St. Helens.

V. 221

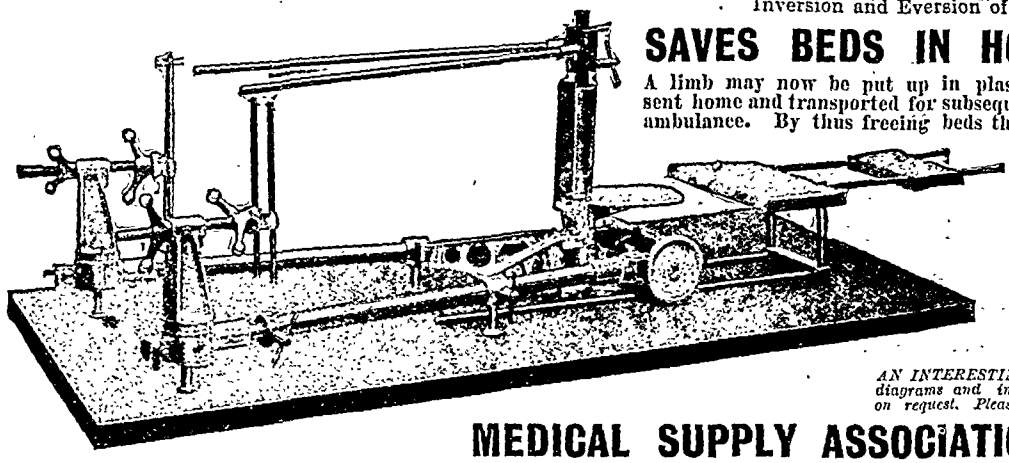
An IMPROVED and MODIFIED

Portable Traction Apparatus

An exceedingly efficient and convenient apparatus for putting up in plaster the lower limbs or trunk; also when applying bone plates or Parham and Martin's Bands to long bones of the lower extremity. Provides the more essential movements of expensive and bulky Orthopædic tables at a fraction of the cost.

Quickly adaptable for the following positions:

Extension of whole lower limbs.
Movements about hip-joint:
Abduction to any degree—
Hyperextension—Flexion—
Internal and External Rotation.
Flexion of knee-joint.
Inversion and Eversion of foot.



SAVES BEDS IN HOSPITALS

A limb may now be put up in plaster, the patient sent home and transported for subsequent treatment by ambulance. By thus freeing beds this new apparatus saves its cost many times over.

Folds compactly for storage or transit in plywood case 35 in. × 15 in. × 11 in.

AN INTERESTING LEAFLET giving diagrams and instructions, post free on request. Please ask for a copy.

COLLENDER'S SPLINTS

(Patented in the Leading Countries of the World)

An evolution of the Thomas Splint—all the advantages of the Thomas Splint are preserved, with many important improvements, additions, and modifications.
They are supplied in strong fitted case, and enable 10 fractures simultaneously to be put up in any position obtainable by Thomas arm or leg Splints.
They provide the most modern methods of accurate extension, and safe transport of the patient is assured. Complete splints suited to limbs of any dimensions can be constructed in a few minutes from the component parts.

All members are interchangeable, standardised, numbered, and replaceable. They are made of Duralumin, which is untarnishable, exceedingly light in weight, and of great tensile strength. They can be immersed in sterilizing fluid without injury and can be used repeatedly.
Collender's Splints will be found invaluable for Hospital Emergency work and particularly to District Surgeons, Mines, Ranches, Lumber Camps, Railways, Shipping Companies, Industrial Plants, and all places remote from surgical help.

INTESTINAL SUBINFECTION

SALVITAE is the key whereby the physician may control elimination and alkalinization, thus dealing fundamentally and effectively with Intestinal Subinfection, Toxæmia, Acidosis, Uric-acidæmia, and Constipation.

It is indicated in a large number of disorders characterized by, and more or less dependent upon, faulty metabolism, imperfect elimination, and disturbances of the acid-base equilibrium of the body.

Samples and Literature on request to Sole Agents:
COATES & COOPER,
41, Great Tower Street,
London, E.C.3.

New York.

VERONIGEN

A liquid preparation of the Hypnotic Barbitone or Diethyl-barbituric acid has long been desired as a useful means of procuring sleep. When given in reasonable doses it is claimed that it does not produce any toxic symptoms whatever, nor is cumulative in action, and in ordinary cases of insomnia, one fluid drachm of VERONIGEN is sufficient dose for an adult. As a preventive of post-operative vomiting, one to two fluid drachms of VERONIGEN may be given one and a half to two hours before general anæsthesia is produced, and as a result much less of the anæsthetic is required. As BARBITONE has a slight diuretic action, the mixture can be used when the heart is weak. Where sleeplessness is a concomitant of pain, rest and relief can frequently be obtained by the administration of one drachm of VERONIGEN and two drachms of ELIXIR ACID. ACETO-SALICYLIC (Hewlett's).

DOSE FOR ADULTS.—One fluid drachm diluted, one hour before going to bed.
For Nervous Sleeplessness in Children.—10 to 20 minims diluted.

VERONIGEN. Price 10/6 per lb. In 5, 10, 22, 40, and 90 oz. Bottles.

Introduced and Prepared only by **C. J. HEWLETT & SON, LTD.** Wholesale and Export Druggists
35-42, CHARLOTTE STREET, & 83-85, CURTAIN ROAD, LONDON, E.C.2.

FERRIN

(SQUIRE)

SOLUTION of IRON and ARSENIC.

Specially prepared for hypodermic or intramuscular injection. It is a valuable antiperiodic.
Particularly indicated in Lymphadenoma, Lymphatic Leukæmia, Secondary Anæmia following malaria, and where gastric conditions do not allow oral administration of iron.
In 1-oz. bottles and in sterilettes (1 c.cm.—approximately 17 min.). The sterilettes are supplied in boxes of 12.

Successfully Prescribed in milder cases

The active substances of the extracts from cone-bearing pine trees (Pinus silvestris, Abies alba, Pinus montana) is found in an oily substance commonly known as pine oil.

Novopine Sparkling Pine Bath Tablets contain this oil in a convenient form and an effervescence is introduced to facilitate successful solution in the bath. Their therapeutic value lies in their action on skin, lungs, and heart. For, in addition to the direct action through the pores of the skin, the ozonic aroma given off is automatically inhaled during the taking of a hot bath.

Besides their general cleansing and health-giving properties, they have been found especially beneficial as a remedy against nervous heart diseases and kindred disorders.

Samples on request from Natural Products Ltd., 40, Furnival Street, E.C.4.

DOCTOR'S CHINA TEA

FOR many years Doctors have recommended our China Tea to Invalids and Dyspeptics when ordinary tea was out of the question. The Medical Press, too, has commented frequently upon the merits of this particular blend—and so we call it DOCTOR'S China Tea.

It is a perfect blend of the finest China leaf with all excess tannin eliminated.

Invalids and dyspeptics can drink it with no ill effects.

HARDEN BROS. & LINDSAY, LTD.
(Dept. 153), 30/34, Mincing Lane, London, E.C.3.

Intestinal Disinfection

MUCOUS AND OTHER FORMS OF COLITIS

CONDITIONS of Colitis occur at all ages, and lead to much suffering, ill-health and chronic invalidism. They are caused by a great variety of bacteria, which, owing to a loss of resistance on the part of the mucous membrane of the colon, maintain a chronic infection, with inflammation of this portion of the intestinal tract.

Vaccine therapy is frequently tried in this condition with disappointing results, as it is pure chance if the causative organism is isolated from the host of bacteria present.

The rational treatment is obviously to administer an efficient germicide which will attack and destroy *all* the bacteria present. Kerol is the one substance which possesses this power, and its administration has cured many a case of mucous colitis.

For intestinal disinfection, use KEROL CAPSULES (keratin-coated); they contain 3 minims of Kerol. One to three capsules may be given three or four times a day after meals.

Please send for Literature and Samples, which will be sent free to any member of the Medical Profession.

ALOCOL

Colloidal Hydroxide of Aluminium

THE increasing prevalence of gastric ulcer and hyperchlorhydria has produced an advance in the treatment of these diseases.

"Alocol" (Colloidal Hydroxide of Aluminium) provides an antacid medicament far superior to subnitrate of bismuth, bicarbonate of soda and other alkalis. These merely afford a certain degree of ease, without bringing about a permanent relief of the condition.

"Alocol" absorbs the excess of hydrochloric acid without interfering with the normal antiputrefactive function of the gastric juice or harmfully affecting the processes of nutrition.

"Alocol" has been subject to extensive clinical trial, and literature giving full particulars of the results will be gladly sent to medical men on request.

Dimol Treatment of Dysentery

EXTRACTS FROM LABORATORY AND CLINICAL REPORTS

IN VIVO

"I have nothing but unqualified praise for the effects of Dimol in the series of cases in which I used it, including a wide variety of intestinal intoxications from mild but persistent diarrhœas . . . to fulminating dysenteries, with passage of large sloughs and great hæmorrhage . . . Accept my hearty congratulations on the discovery of what looks like a specific for control of the poisonous flora of the intestines."

——, M.B., B.Ch., Malay States.

IN VITRO

"Cultures of *B. dysenteriæ* Shiga and *B. dysenteriæ* Flexner were submitted to the action of the intestinal disinfectant Dimol. Five c.c. of the Dimol lavage solution was taken and to it was added 0.2 c.c. of a filtered broth culture of the above organisms; cultures were taken at varying time limits from 2½ minutes, and all these cultures remained sterile. This lavage solution, therefore . . . is capable of killing dysentery bacilli in 2½ minutes."

——, C.I.E., M.B., B.Ch. (Camb.), Major, I.M.S.

After long and thorough investigation, Dimol pulverettes are now supplied by the Admiralty for use in His Majesty's Ships and Royal Naval Hospitals.

The efficiency of Dimol in the treatment of *intestinal disabilities of bacterial origin* is conclusively told in the interesting clinical reports which, together with a brochure dealing with the pathological significance of the intestinal toxæmias, will be sent to any medical man on application to the

INSULIN 'A.B.'

TRADE A B MARK Brand

"A.B." Insulin was the first British Insulin available for use by the Medical Profession and after almost five years retains its reputation as the Insulin which can be relied on to give consistently satisfactory results. The supremacy of "A.B." Insulin is due entirely to the stringently high standards of purity, therapeutic efficiency and stability self-imposed by its manufacturers.

"A.B." Insulin connotes:

Uniformity of unitage.
Full potency and stability in all climates.
Purity and complete sterility.
Absence of reaction-producing proteins with consequent noteworthy freedom from *unpleasant by-effects.*

The activity of "A.B." Insulin is guaranteed by the most complete physiological tests and standardisation on the basis of the accepted unit. Before issue, each batch is passed under the authority of the *Medical Research Council.*

These classical symptoms of inflammation

RUBOR CALOR
TUMOR DOLOR
Effectively Controlled with
Antiphlogistine

FOR over a third of a century, leading practitioners in every part of the civilized world have considered Antiphlogistine as "Inflammation's Antidote" and as synonymous with the prompt alleviation of pain and congestion, both superficial and deep-seated.

Acute Laryngitis in Children

Inflammation of the larynx is always a serious affection in childhood, and produces acute symptoms—dyspnoea, cyanosis, and tendency to spasm—more quickly than in adults. Hot applications of Antiphlogistine over the larynx will be found a distinctly valuable auxiliary to the general treatment.

Parotitis

In inflammation of the parotid glands, associated with congestion, swelling and infiltration of serous fluid, hot Antiphlogistine applied to the affected area will hasten the decline of the parotid symptoms, restore the gland to its normal condition, and add to the greater comfort of the little patient.

THE DENVER CHEMICAL MFG. CO., LONDON, E.3

"SMILER"

The Choice of a Dried Milk for Infant Feeding

The busy Medical Officer and Practitioner are often confronted with this important problem in the course of their duties. The decision must be based, above everything else, on scientific and logical considerations.

Dried milks are prepared mainly by two processes—the Spray and the Roller. In the former, the milk is subjected to a long heat treatment at temperatures varying from 45°-70°C., and finally sprayed in a blast of hot air. In the latter, the milk is subjected to a temperature of about 95°C. for 2½-5 seconds, on specially constructed rollers.

Scientific and authoritative evidence on both processes is to the effect that, while the Spray method results in a powder which is more soluble, and with the fat in a finer state of division, the curd is, like that of the original milk, still heavy and indigestible. There is some precipitation of the calcium salts, the vitamins have been partially or completely destroyed, lactic organisms, and, *ipso facto*, other organisms whose lethal temperatures are at the same, or at higher temperatures, are still present, and of economic importance, the keeping properties of the powder are limited. The Roller process yields a powder in which the fat emulsion is not so perfect, and the lactalbumen partly coagulated, but on the other hand gives a curd like that of breast milk—soft, flocculent and easily digestible. Moreover in roller powder the vitamins of the original milk are intact; it is practically sterile, and possesses far better keeping qualities.

Cow & Gate Milk Food

Cow & Gate is prepared by a special Roller process under the most scientifically controlled conditions, from the milk of the rich pasture lands of the West Country. Its value as an Infants' Food has been proved practically by the Medical Profession for over a quarter of a century.

The makers will gladly supply samples and any further information, if required, and wish to remind Members of the Nursing and Medical Professions that the Cow & Gate Laboratories are always at their disposal for experimental work in connection with Milk Foods, and that they will be delighted to arrange visits to their factories in the West of England at any time.

Vita-Weat—the perfect "staff of life"

Analysis and tests of Vita-Weat, the British whole-wheat crispbread, show that it possesses in a marked degree the six essential constituents—carbohydrates, fat, proteins, mineral salts, water, *and the essential vitamins.*

100% Whole Wheat.

Being made from the whole wheat berry, from which nothing has been removed in manufacture, Vita-Weat yields the highest natural percentage of cereal proteins, and by the process of manufacture the starch present is rendered easily available for the solvent action of the amylolytic ferments of the human digestive juices.

Further, Vita-Weat is specially valuable as a natural stimulant to peristaltic action of the intestines, and when forming a suitable proportion of the daily diet effectively counteracts constipation.

Vitamins A, D, and B.

The dry condition of Vita-Weat is of distinct advantage in cases of flatulence in which moist foods are largely contra-indicated, and the crisp character of the sections also helps to reduce the intake of soft foods, giving the teeth and masticating muscles something to do and ensuring complete and thorough salivation of the food bolus.

Vita-Weat crispbread presents the whole wheat berry in a concentrated, attractive and digestible form with the Vitamins A, D & B in an active condition, and it forms a valuable addition to rational diet, presenting a dainty and advantageous alternative to soft wholemeal or white bread.

Food Poisoning—
The Kaylene Treatment

The following letter has been received recently.

MESSRS. KAYLENE, LTD.

DEAR SIRS,

I am in receipt of your sample of Kaylene, for which I thank you. I do not dispense and do not wish to be without some in the house.

My last sample was used on a patient suffering from acute Ptomaine poisoning following a meal of shell fish (mussel) at 10.30 p.m. Symptoms first appeared at 12.30 a.m., and when I saw him at 3.0 a.m. he was vomiting blood and passing almost pure blood per rectum. He had commenced cramps and nervous twitchings which would shortly have gone on to tonic convulsions. He was very collapsed and had a weak pulse. I gave him **only** Kaylene in cold water, one drachm every quarter of an hour, from 3.0 until 8.0 a.m., when I felt it safe to leave him. For the next two days Kaylene was given every one to two hours, and was then followed by Kaylene-ol. No other medication of any sort was used, and he made an excellent recovery. This follows a somewhat similar case which I treated at the end of last year.

Your excellent preparation should supplant Bismuth for any purpose.

Yours faithfully,

Physician to ———. ———, M.B.

Literature and supply for clinical trial obtainable from the manufacturers.

Kaylene Ltd

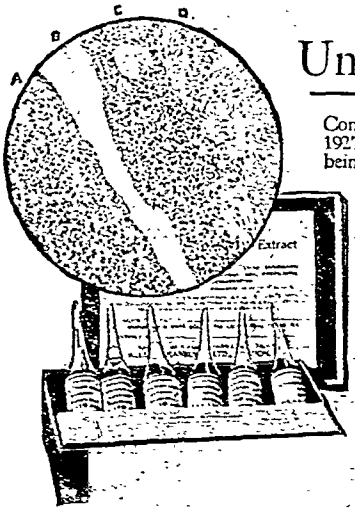
Trade **'PITIBULIN'** Mark

Denotes

Unvarying Pituitary Extract



Conforming to the requirements of the Therapeutic Substances Regulations, 1927, 'Pitibulin' is prepared according to the official standards, its activity being now expressed in terms of the accepted unit.

As heretofore, 'Pitibulin' maintains the stringently high criteria of therapeutic efficiency, safety in use and stability, self-imposed by its manufacturers—qualities which have given it its high place in the esteem of physicians.

'Pitibulin' retains its reputation as the Pituitary Extract which can be relied on in emergency.

Micro-photograph of section of Pituitary showing

(A) pars anterior **(C) pars intermedia (posterior lobe)**
(B) inter-glandular cleft **(D) pars nervosa (posterior lobe)**

'Pitibulin' is supplied in Ampoules containing 2.5, 5, and 10 units.

Literature giving fuller particulars of the therapeutic applications of 'Pitibulin' will be sent on request.

VITAMINS A, B & D

HAVE ALWAYS BEEN IN CADBURY'S MILK CHOCOLATE.

Fresh milk only is used in Cadbury's Milk Chocolate, which is made by a distinctive process incorporating the fresh milk direct with the chocolate.

By this process, the important Vitamins A, B and D, natural to fresh milk, are retained.

Owing to its concentrated form (there are 1½ glasses of milk in every ½-lb. cake) the chocolate is appreciably richer in Vitamin D than milk itself. Further, it contains the whole of the bone-forming calcium and phosphates present in the milk. All the essentials of an anti-rachitic food are contained in Cadbury's Milk Chocolate.

The dietetic value of milk has always been recognised by the medical profession—a convenient and concentrated form is Cadbury's Milk Chocolate.

This chocolate is sold in 2d. Bars, 6d. Packets, and 1/- ½-lb Blocks.

Reminders and Suggestions

IODOBESIN → **OBESITY**

Pluriglandular Total Extracts with Iodalbumin.

A safe and useful adjunct in the treatment of Obesity and other troubles due to deficient endocrine activity.

In bottles of 60 and 120 Tablets.

MYCOLACTINE → **CONSTIPATION**

A combination of Bile Extract, Yeast, and Lactic Ferments.

An educator of the bowels and an intestinal disinfectant in alimentary toxemias and intestinal stasis.

In bottles of 50 Tablets.

Observations ON DIAGNOSTIC AND OTHER ERRORS IN QUESTIONS OF VENEREAL DISEASE.*

BY

L. W. HARRISON, D.S.O., M.B., CH.B., F.R.C.P.ED.,
DIRECTOR, VENEREAL DISEASES DEPARTMENT, ST. THOMAS'S HOSPITAL.

THE subject of this paper was suggested to me by a run of such cases as the following.

A man of good position asked me to examine him for gonorrhoea. He said that a year previously he had contracted gonorrhoea, which had cleared up completely without any complication. About three months before I saw him he had married, after passing careful tests by a conscientious specialist. A month after marriage his wife developed a Bartholinian abscess, and on the strength of this the husband was told that he had infected his wife with gonorrhoea. You can imagine his distress. I examined him three times and failed to find any evidence of disease in his urethra or adnexa. A complement fixation test for a gonococcal infection carried out by Dr. Osmond gave a completely negative reaction, and I had no hesitation in saying that he was not suffering from gonorrhoea. On my advice, his wife was seen by Dr. Margaret Rorke, who reported that she could find absolutely no sign of gonorrhoea, and that the bacteriological tests strongly suggested a *B. coli* infection as the cause of the Bartholinian abscess.

You will realize that there were the makings of a marriage wreck in this history, and all from the assumption that a Bartholinian abscess spells gonorrhoea, from failure to make bacteriological tests of the abscess pus, or to examine other parts of the genito-urinary passages for confirmation of the suspicion.

In the course of a few years a specialist in venereal diseases meets a respectable number of cases in which mistakes in diagnosis have been made through failure to take even a little trouble over examination of the patient, and the consequences are often so distressing to the patient, so full of possibilities for wreckage of domestic happiness, that I thought it would not be a bad thing to make some of them the subject of a contribution to the proceedings of this Section. Fearing lest I should omit mention of some important errors, I asked my colleagues in the St. Thomas's Hospital Venereal Diseases Department to give me the benefit of their experiences in this matter, and I am indebted to them for some which I should probably have overlooked.

In questions of gonorrhoea it may sound surprising, but ordinary balanitis is sometimes diagnosed as gonorrhoea. I remember a case in which the mother of a boy at a public school was requested to remove him because the school doctor said he had gonorrhoea. He had simple balanitis. Dislike of examining the penis at close quarters must account for numbers of cases commonly seen in which a syphilitic chancre at the meatus or within the fossa navicularis has been diagnosed as gonorrhoea. It is quite a common thing to see cases of tertiary syphilis in which the patient denies any history of a sore, but admits gonorrhoea. I cannot help thinking that in a number of these, in which the patient says that the discharge was only slight and rather watery, the trouble was due to an intra-urethral chancre. The omission of a microscopical examination leads to many cases of urethritis which are due to chemical causes, to constitutional disturbance, or to infection with diphtheroids, staphylococci, streptococci, *B. coli*, or organisms other than gonococci, being treated as gonorrhoea with potassium permanganate irrigations or with one of the fifty-odd preparations of silver which have been put on the market for this complaint. Sometimes a microscopical examination has been made, but only a simple stain has been employed, and a few streptococci inside pus cells have been diagnosed as gonococci. Sometimes a so-called Gram's stain has been used, but the violet has been dissolved out of Gram-positive cocci by prolonged application of methylated spirit, and the process of conversion of Gram-positive cocci into seemingly Gram-negative ones has been completed by a prolonged application of such a stain as carbol-fuchsin.

On the female side vaginal discharges due to a multitude of causes other than gonococcal are commonly diagnosed as gonorrhoea. On the other hand, I have known scores of cases in which a woman who has clearly infected a patient has gone to a practitioner and been passed as free from gonorrhoea on the strength of one naked-eye examination, or at most a single microscopical test. It has been forgotten that a cervical canal may be swarming with gonococci without a pus cell being present, or that gonococci may only intermittently come to the surface of the cervical canal, and that not one but many examinations are necessary to exclude gonorrhoea in a woman.

I have seen a number of cases in which the sudden appearance of a urethral discharge, due to the breaking open of a prostatic abscess which has formed quietly, has been diagnosed as gonorrhoea solely on the appearance of the discharge, or on badly stained microscopical specimens. Most of the cases have been in married men who, for one reason or another, had for some time suspended sexual intercourse. I imagine that their prostates had for years been secreting pus, but sexual intercourse had kept the foci draining. The micro-organisms have been in different cases staphylococci, *B. coli*, *B. lactis aerogenes*, *B. pyocyaneus*, *B. proteus*, and others, but not gonococci. One would think that in such a case common sense would dictate a microscopical examination of the pus; and, if the patient is married, as he often is, one might think it not a bad idea to make an inquiry as to the wife's condition before thrusting the patient into hell with a diagnosis of gonorrhoea. It may be worth mention here that a non-gonococcal prostatitis can cause symptoms which simulate typhoid, and I have known of some cases being treated for this disease even after the abscess has burst.

Epididymitis, especially if accompanied by a urethral discharge, seems often to write the word gonorrhoea in the practitioner's mind to the exclusion of every other possible diagnosis—for example, an infection with *B. coli*, or even *B. tuberculosis*. Yet only a few more minutes spent over the examination would serve to avoid the error if the case is not gonococcal. I have known some cases of right-sided gonococcal epididymitis diagnosed as appendicitis. The patient suddenly had an acute pain in his right iliac fossa, his temperature went up to 103° or 104° F., and perhaps he vomited. But his right rectus was not rigid, he did not look like an appendix case, and pressure on his cord as it crossed the ischio-pubic ramus caused very severe pain. By these signs, when I was in charge of a very large number of in-patients suffering from gonorrhoea, I saved quite a number of innocent appendices from removal and had none of general peritonitis.

In cases of arthritis, iritis, and similar troubles often classed as gonorrhoeal, microscopical and cultural tests often fail to discover the gonococcus, and the complement fixation test with a gonococcal antigen is negative. On the other hand, my colleagues and I have seen a fair number of cases of gonococcal arthritis soaked with salicylates, or with potassium iodide, gonorrhoea not having been thought of, or having been excluded on the score of naked-eye examinations.

I owe much to the help of the microscope, to the culture tube *containing a properly made medium*, and to the complement fixation test. Properly used they save one from many pitfalls. They do not dispense with ordinary clinical tests, but to deny oneself their help is to walk blindfolded.

Turning now to cases of chronic gonorrhoea, I think the number of innocent prostates and seminal vesicles which have been massaged for trouble which a careful examination would have localized in the anterior urethra must be many thousands. Sometimes it is because in the textbook it says that prostatic massage will often clear up a chronic case of gonorrhoea, and so, without further examination, the prostate is massaged. Sometimes a specimen of prostatic secretion is examined, but it has flowed along a urethra cleansed only partially with a stream of urine, not previously washed down by irrigation as it should be, and so the prostatic secretion contaminated with pus picked up in the urethra has been found to be pathological,

* Made in opening a discussion in the Section of Venereal Diseases at the Annual Meeting of the British Medical Association, Manchester, 1929.

Omission of a urethroscopical examination leads often enough to months of treatment which a touch with a cautery point on one discharging follicle would clear up in a few days. Sometimes I have destroyed a small paraurethral canal and so ended a chronic urethritis which has kept a patient miserable for years.

Chronic urethritis is notoriously difficult to clear up, but I am certain that, if more pains were taken to examine and no method of examination omitted—microscopically, cultural, complement fixation, naked-eye inspection both outside and inside, as well as palpation with fingers and through the medium of instruments—much unhappiness of patients would be avoided. And a patient with a chronic urethritis is generally an unhappy man, far more so than one with a chronic catarrh of the nose or bronchi, and it is important to cure his urethritis even though it may not be physically of any moment.

In questions of syphilitic infection, I would mention first the pernicious practice of commencing the treatment of early cases on mere suspicion—to give the patient the benefit of the doubt as is often said. Those who commence treatment on such principles without having verified the diagnosis by bacteriological methods cannot have much imagination of the effect of a diagnosis of syphilis on the patient's mind. Every syphilologist must have seen numbers of cases in which the patient gave a history of a genital sore which was not examined microscopically, and on the strength perhaps of what was called a weakly positive reaction, or even without any blood test at all, treatment was commenced. The history has left one with a very considerable doubt as to the correctness of the diagnosis, but in most cases one has not dared now to suspend the treatment because the negative reactions might be due to the treatment already given, even though this has been trivial. In some cases, however, I have been so convinced that the original diagnosis was wrong that I have suspended treatment. The reactions have remained negative, but the patient has not been freed of anxiety about his future; he has continued to be tested regularly, and when he has married, if one of his babies has snuffled a little, had a rash of any description, or any ailment whatever, he has worried over the possibility that I was wrong and that he had after all transmitted the disease to his offspring. The pitiable condition of his mind is due to the fault of the original man who commenced treatment to give him the benefit of the doubt. There need be no doubt. With bacteriological aids properly employed the diagnosis of an early case can be made with certainty, and, as a rule, rapidly. Promptitude in commencing the treatment of an early case is certainly important, but I am sure that it is not so important as certainty of diagnosis.

I have mentioned diagnosis on the strength of a serum reaction which is called "weakly positive." In the *Journal of the American Medical Association*, 1926 (vol. 87, p. 1351), there appeared an article by J. H. Mitchell entitled "Menace of the slightly positive Wassermann reaction," with which I am entirely in sympathy. The author related cases in which a false diagnosis of syphilis had been made on the flimsy evidence of a weakly positive Wassermann reaction alone, or in conjunction with some non-specific dermatosis having a superficial resemblance to syphilis, such as pityriasis rosea or lichen ruber planus. The result had been the firm establishment of that intractable disease syphilophobia. Sometimes marriage engagements had been broken, and at others divorce proceedings been instituted, in consequence of a dishonest or an ill-trained practitioner founding a diagnosis of syphilis on such a reaction. I am sure that every syphilologist of standing could relate similar cases, and I am convinced that the term "weakly positive" should never be applied to any reaction which is weaker than the pathologist's standard for a diagnosis of syphilis. I have always maintained that, for reactions which the pathologist considers insufficiently strong for a diagnosis of syphilis, the term "doubtful" should be employed, and if I got a report that a specimen gave a "weakly positive reaction," I should ask the pathologist if he meant by it such a reaction as is given only by syphilitic serums or one given sometimes by non-syphilitic.

A false diagnosis of syphilis is sometimes based on a single positive reaction with clinical signs which are only faintly suspicious. As an example I have in mind a patient I once saw who had been diagnosed as syphilitic on the strength of an ulcer on the lip and a single positive reaction. No *Sp. pallida* had been found in the secretion from the ulcer, there was no adenitis, and the whole history made a diagnosis of syphilis only the faintest possibility. The patient had attempted suicide after being told he was suffering from syphilis. Another specimen of serum was sent to be tested in the same laboratory and this time was reported as negative. I have always taught that, if a report that a serum reaction is positive is not supported by the clinical data, another specimen of blood should be sent. It is no disparagement of the care taken in laboratories to prevent errors to say that every now and again one will occur; specimens may be confused, a dose of complement may be omitted from a standard tube, a piece of cigarette ash may fall into a standard tube, or a number of other little things may happen which result in a normal serum being reported as positive. Such accidents do not happen once in a thousand tests, but, when they do happen, be sure it will be the specimen in which it is most important that no mistake should be made. If I have the least doubt of a result, I have another specimen tested.

As a good example of a mistake which can happen from jumping to conclusions from a naked-eye examination the following was related to me by my colleague Dr. Anwyl Davies. A person was sent to him with a diagnosis of primary sore on the penis and a secondary rash on the abdomen. Examination showed an oval ulcer on the glans penis with a tender inguinal gland. There was an erythematous rash on the abdomen below the umbilicus, and the combination might easily have been mistaken for syphilis. A prolonged search failed to discover *Sp. pallida* in the secretions, and close questioning revealed that in treating honeycombs with a chemical called "beemol," used to prevent Isle of Wight disease, some had dripped on to his waistcoat and passed through this to his skin. The subsequent history proved this to be the correct explanation of the lesions.

The mention of chemicals reminds one that a very fair imitation of a primary sore can be produced by self-applied caustic stick, and a burn of a lip by a cigarette has been diagnosed as a mucous patch. I once spent an afternoon on a medical board cleansing the record of an officer who had been diagnosed as syphilitic and had protested. The diagnosis had rested on what was said to be a mucous patch on the posterior pharyngeal wall. There was absolutely no evidence of syphilis, but there was a narrow stream of mucus stealing down the middle of the posterior pharyngeal wall, and with only a little book-learning for guidance one might have said it was a snail-track ulcer. Of other conditions in the throat Vincent's angina and diphtheria are, of course, common sources of error.

Scabietic runs on the glans penis are quite commonly diagnosed as primary chancres, especially if they have become a little crusted, and, on the other hand, a cervical chancre on the cervix is sometimes diagnosed as a gonorrhoeal erosion.

Warty conditions about the genitals are a great source of error. Numbers of cases of syphilitic condyloma have been treated for weeks with an ointment suitable for haemorrhoids. Sometimes the patient has not even been examined, and the ointment has been prescribed on the patient's request for "something for piles." On the other hand, many warty conditions have been diagnosed as syphilitic because presumably they were warts, and syphilitic condylomata are warts. In most of these cases, apart from the fact that a careful examination is usually sufficient to distinguish a syphilitic condition from a non-syphilitic, a microscopical examination of the serum from any early syphilitic lesion will usually settle the matter.

Perhaps a less serious error is to diagnose every syphilitic lesion on the genitals as a primary ulcer. It may be awkward then if the patient relates a history of syphilis a few years old and, the lesion being really a gumma, the serum reactions stubbornly remain positive.

Extragenital chancres are commonly overlooked. I have known of a tonsil which was the seat of a chancre being enucleated and the same patient being sent later to a fever

hospital for German measles, the true diagnosis being reached only when the eruption did not clear up in the time usual for measles. Chancres of a terminal phalanx are usually diagnosed as whitlow until a rash appears. The worst error of this kind I ever saw was in a medical officer who was looking after syphilis cases during the war. He allowed his finger to be treated for whitlow, and his tonsils to be cauterized for ulcers, and then went peacefully to hospital for measles. It dawned on him that he had accidentally contracted syphilis, when the measles rash was succeeded by a profuse papular syphilide.

The error of excluding syphilis may be made from the absence of any history of a primary sore. A rather remarkable case of this kind was a nurse who pricked her finger in cleaning up after an operation. She dipped the finger in antiseptic, and no sore appeared, as I have known to happen after the application of an antiseptic in other cases. An axillary adenitis appeared on the side of the pricked finger, and it was diagnosed as tuberculous. Subsequently a general, rather painful adenopathy appeared, and she was treated with ultra-violet rays about three months after the accident. The application of the rays was followed by a rash, which was said to be due to an overdose, but a significant thing was a discoloration of the neck, which appeared at the same time, and was easily recognizable fifteen months later, when we first saw her, as a syphilitic leucodermia. This dated *the infection. Naturally, all other sources of infection* were excluded by careful examination.

A common mistake is to assume that in a patient with positive serum reactions all abnormalities are themselves syphilitic.

An unusual case was one in which a patient came to me with a history that he had been treated for secondary lesions between the toes. He had previously suffered from a gumma on the chest wall, but the peculiarity of secondary lesions succeeding tertiary did not seem to have struck his medical adviser. He had received a course of treatment, but the lesions remained unaffected, so the patient thought he was not being properly treated. A little examination showed that the trouble was due to trauma, and from one of the sores between the toes I picked out a small spicule, which I could not understand until the patient told me he used a loofah in cleansing his feet.

Tertiary syphilis of the tongue has led to many epitheliomata there being overlooked, and I would caution against being misled by a temporary improvement following administration of arsenobenzene preparations in these cases. The tendency to regard all lesions on the genitals as venereal in origin sometimes leads to an epithelioma of the penis being diagnosed as gumma.

Gummata of the testicle have fairly often been removed under a diagnosis of new growth. In one case which I remember I feel sure that the practitioner and also the pathologist were misled by the blameless life of the patient, and it was not until many months later, when an undoubted gumma occurred elsewhere, that the blood was tested.

I think the tendency in nervous diseases is to think of syphilis and in cardio-vascular disease to forget it. At least quite a number of cases of nervous disease due to causes other than syphilis have been sent to me for treatment, and I have seen a fair number of cases of syphilitic myocarditis in which I wished my predecessors had thought of syphilis earlier and left me with less of a wreck to treat.

In questions of treatment it is always a source of wonder to me that there are so many people who give only partial treatment if there has been a doubt about the diagnosis. They would probably agree at once that a thing cannot both be and not be, but yet they act as if it could.

In patients under antisyphilitic treatment failure to diagnose certain skin rashes as due to arsenic and continuance of the treatment has led to most tragic results; so much so that one would emphasize with all one's strength the advice to take serious notice of any dermatosis in a patient undergoing arsenobenzene treatment, however trivial the skin affection may seem. One should consider most seriously whether or not this is arsenical, and decide on continuance of this form of treatment only on firm conviction that it is not. Otherwise the result may be a dermatitis from which the patient may die, or recover only after a long and trying illness. I ought to mention here that bismuth sometimes causes a troublesome dermatitis, though it is very uncommonly so acute as can be one due to arsenobenzene.

I have thus attempted to set out some of the commoner errors in diagnosis in questions of venereal disease. The subject could be expanded to far greater length, but even if space would permit of this the result would only emphasize still more the principle that, in venereal diseases as in others, one must look for and gather all the evidence which will bear on the diagnosis. And, having gathered the evidence, one must sift it with judgement and common sense. If this discussion leads to some reduction in the wretched victims of wrong diagnoses—the poor devils who go through life under the shadow of an anxiety for which there is no real reason—it will have done some good.

THE PRESENT POSITION OF SILICOSIS IN INDUSTRY IN BRITAIN.*

BY

E. L. MIDDLETON, M.D., D.P.H.,

H.M. MEDICAL INSPECTOR OF FACTORIES.

DURING the last two decades the subject of silicosis has become increasingly popular as a topic for contributions to medical literature, and the treatment of the subject has been undertaken from so many different angles that it seems to be an act of supererogation to return to this topic at the present time. There are, however, one or two aspects of the subject which I have felt should be brought directly to the notice of the medical profession, and these are concerned with (1) the occurrence of the disease in the various industries throughout this country; (2) the manifestations of the disease as it presents itself to medical practitioners; and (3) the legislation which has been brought into being within recent years.

For the purposes of this paper I will assume a general knowledge of the etiology, symptomatology, and pathology of the disease, but those who have made a special study of the subject will pardon me if I review briefly a few points on this aspect of the subject.

ETIOLOGY.

Silicosis is produced by the inhalation of particles of silica breathed in with the atmospheric air in the course of a person's employment. In silicosis, properly so-called, the silica is in the form of free dioxide of silicon (SiO_2), in the form of quartz, flint, chert, etc. The particles to produce the disease must be inhaled into the ultimate pulmonary tissue—that is to say, into the alveoli—and must therefore be of a degree of minuteness which will permit of their free passage in the mid-current of the air through the upper respiratory passages and the finest bronchial tubes. Many of the particles return with the expired air, but a proportion of them will adhere to the alveolar walls, as well as to the walls of the bronchi. In the latter case particles are caught in the mucus and removed by the action of the cilia. Those particles which fall on the walls of the alveoli are taken up by phagocytes, which move towards the lymph channels and interspaces in an effort to remove the silica. Where the amount of dust is small the action of the phagocytes is likely to be effective, but where it is great this action is imperfect, the phagocytes, overloaded with dust, becoming detained in their progress. The silica acts on the cells so that they lose their motile power. The result is aggregation of these cells in the lymphatic channels, especially the perivascular and peribronchial lymphatics. A deposit of these cells produces a reaction in the surrounding tissue; fibroblasts are produced which change ultimately into fibrous tissue, and so long as the action of the silica proceeds the formation of fibrous tissue continues, from a centre towards an extending periphery. The fibrous tissue undergoes condensation and contraction, and, pulling on the remaining lung tissue, produces distortion with loss of function. It seems likely that blood vessels are obliterated by compression from the perivascular fibrosis before the corresponding bronchi are obliterated, and I have thought that this might explain the absence of cyanosis in chronic forms of silicosis, in

* The opening paper of a discussion in the Section of Occupational Diseases at the Annual Meeting of the British Medical Association, Manchester, 1929.

contradistinction from respiratory diseases of a more acute type, in which the vessels remain patent after the corresponding area of lung tissue has ceased to carry out its aerating function.

PATHOLOGY.

The pathological characters of a silicotic lung vary according to the progress of the disease. When this is of a very chronic type there are apt to be large areas of dense tissue, extremely hard and black on section, and showing no remnant of lung tissue. These areas may be two or three inches in extent, especially about the upper or middle zones of the lungs, and they are associated with extensive pleural thickening and adhesions. The remaining lung tissue between the nodules or solid masses of fibrous tissue is usually in an extremely emphysematous state. In such lungs it is common to find small foci of tuberculosis embedded in the dense fibrous tissue. These may show excavation or cavitation, but in some cases this is the only macroscopic manifestation of the disease. In other cases tuberculosis of the usual ulcerative progressive type is found, and this may be the ultimate cause of death. In still other cases no massive fibrotic areas are found, but throughout the whole of both lungs nodules are present, varying in size from one or two millimetres to about a centimetre in diameter. On the pleural surface the nodules are represented by minute elevations, like sago grains, covered with a whitish layer owing to the thickened pleura. They feel shotty to the touch and are intensely hard. Where the lungs are so free from pleural adhesions that they can be removed from the chest cavity, these nodules on the outer surface of the pleura present an almost characteristic appearance. In fatal cases of this diffuse discrete type of nodular silicosis, where tuberculosis has not supervened and proved to be the cause of death, there are usually found areas of broncho-pneumonia and congestion. There seems no reason to doubt that silicosis may prove fatal without the intervention of tuberculosis.

Microscopic examination of lung sections shows the nodules to be formed in a characteristically whorled arrangement of the fibrous tissue. The oldest tissue is at the centre of the nodule, and often shows a laminated structure with pigmented particles between the fibres. When the particles or masses are large enough—that is, about 5μ—they can be demonstrated by polarized light. Lymphatic glands from the roots of the lungs are enlarged, intensely hard, and on section are black and show fibrous tissue change, and the presence of pigmented particles on microscopic examination.

SYMPTOMATOLOGY.

The inhalation of silica dust is not usually accompanied by evidences of irritation. When free from other dusts of an irritating kind, silica may be inhaled by the workers without any suspicion that they are exposed to dangerous dust, and, indeed, this fact accounts for some of the indifference shown by workers in neglecting reasonable precautions to protect themselves from the risk of inhaling silica dust, and it likewise prevents an employer from suspecting that danger is being incurred by the workers. With regard to symptoms, we must now distinguish between what we might call the chronic form of the disease and the acute form of the disease, but in describing these it must be understood that there is no hard-and-fast line between the two types of cases, so far as we know at present. This is a matter on which light is badly needed. The chronic form is by far the more common. The first symptom is usually dyspnoea, and this may be noticed any time from about five years to forty years or longer after the commencement of the time of exposure. In the production of this symptom two well-known characters of silicosis are important. The first is the cumulative action of silica—that is, each successive dose of silica produces a summation of effects in the anatomical changes of the lung. The second is the latent period which is necessary for those changes to take place. This means that exposure to silica dust is not followed by symptoms immediately, but after a lapse of time, varying from, say, two years to forty years or more, during which fibrous tissue is formed and the function of the lung is interfered with, the symptoms begin to appear. It means also that when a period of exposure to silica dust has occurred these anatomical changes will proceed even though the subject is removed from further inhalation of silica dust. These two facts together are of the first importance in the prognosis of silicosis and in its control. If it be possible to detect the disease at such an early stage that the amount of silica dust already acting on the lung is less than that necessary to produce disability even when the whole of the latent period is passed, it would be possible, by periodic examinations, to remove from the risk persons with this degree of involvement, so that the disease would never develop to a disabling extent. One of the problems remaining to be solved is just that. Is the disease recognizable at a stage when removal from exposure to silica dust will not be followed by disablement? An important factor in this, of course, will be the intensity of exposure—that is, the concentration of dust in the atmosphere. If the dust cloud be dense, a large amount of silica may be inhaled into the lung before the anatomical changes are produced, and in such a way as to render extensive and severe anatomical changes inevitable.

Apart from dyspnoea, other symptoms are those of any respiratory disease, and they depend on the character and degree of secondary infection and the changes resulting in the lung tissue, the bronchi, and the upper respiratory passages. There is one possible exception to this, and that is in what we have called the "acute form" of silicosis. A few such cases have been noted recently. The onset of symptoms occurred from two and a half to four years after first exposure to inhalation of the dust, and, commencing with dyspnoea, there was rapid development of general constitutional disturbance, with pyrexia and acute illness lasting over a few weeks and terminating in death. In these cases cyanosis was a definite well-marked physical sign, and the whole picture of the illness closely resembled that of miliary tuberculosis. It is possible that the presence of an alkali mixed with the silica dust had something to do with the course of the disease in these cases.

DIAGNOSIS.

Three groups of facts must be available to make a diagnosis of silicosis which can be regarded as satisfactory and final. First, the employment history. Silicosis does not occur without exposure to the inhalation of silica dust. It is necessary that the employment history should be exhaustively studied and that no period of employment should be allowed to escape notice, because a comparatively brief period of exposure may be the only determining factor in a case of silicosis, provided that the latent period is accounted for subsequently.

A clinical examination of the patient can never be dispensed with. The symptoms and course of the disease, as stated by the patient or his relatives, are of the utmost value in making a diagnosis. The clinical examination by inspection of the chest, percussion, and auscultation is never so devoid of result as some of the writings on the subject would lead one to believe. The more one studies the subject the more one is inclined to regard the physical signs as being not only detectable but important, especially in prognosis.

In the radiological examination the technique has now become a science in itself, and so many medical men in the tuberculosis service have made themselves masters of this technique that I leave the subject to be dealt with by those who have modern practical experience. The pulmonary radiograph requires different methods from that employed in connexion with other applications of x rays. The test of a good x-ray film lies in the film itself, and provided that it complies with a certain high standard of technical excellence, the interpretation may safely be left to anyone who has an intimate knowledge of the disease and the appearances which the radiograph provides.

PROGNOSIS.

Prognosis depends on (1) the amount of dust inhaled, (2) the period of time over which this acts, (3) the occurrence of infective processes—tuberculous and non-tuberculous. If diagnosis can be made at such an early stage in the disease that sufficient silica has not been inhaled to produce irreparable damage, and so much damage has not been done as to produce disability, then it seems that the disease can be arrested. I know of no curative procedures

other than those to control secondary infections. When symptoms have become established and the patient is still exposed to the inhalation of dust, it seems inevitable that the condition should progress. This has been the uniform experience. The longer the period of exposure before symptoms have developed, that is, the more chronic the type of the disease, the slower will be its progress, and a period of several years may elapse without any appreciable advance being made in the course of the disease, even when partial disablement has resulted. Even in advanced cases, when dyspnœa is severe, a patient may carry on his work, especially work of a skilled and partially sedentary nature, until within a few days of death. In such extremely chronic cases death usually results from broncho-pneumonia or congestion of the lungs—it may be following influenza.

NOMENCLATURE.

Considering the wide distribution of silica in nature—55 per cent. of the earth's crust consists of free or combined silica—and the many uses to which it is put in industry, it is not surprising that the disease which we have under discussion should be widespread. I will briefly attempt to indicate the main industries in which silica is used in such a way that it may be inhaled by the workers and give rise to silicosis. Before entering on this, however, I would like to say a word on the nomenclature of this subject. Legislation has been brought into force within the last ten years in this country to provide compensation for silicosis, and in that legislation the term "silicosis" is restricted to the disease produced by the inhalation of silica dust. It is necessary, therefore, to restrict the application of the term "silicosis" to the disease condition produced by the inhalation of silica dust (SiO_2)—that is, free silica. This does not mean that the silica must be unmixed with other dusts, but it must occur chemically free, as it does, for example, in quartz, flint, chert, quartzose sands and sandstones, granite, and many rocks and deposits in which quartz or silica in another form is found in substantial proportion. There is a tendency to apply the term "silicosis" to fibrosis of the lung produced by various kinds of dust, and there is a danger that it will be assumed, because fibrosis of the lung is produced by the inhalation of dust, that that dust contains silica in some form or other. It seems to me that this is an entirely wrong method of proceeding. Fibrosis of the lung due to the inhalation of dust should be regarded as such, and the dust producing it should be referred to specially.

The word for fibrosis of the lung produced by dust happens to be "pneumonoconiosis," and I feel that one reason why this is not used as much as it ought to be is because of its unwieldy size, and I am going to suggest that the word "coniosis" be used in the same sense, indicating fibrosis of the lung produced by dust. Seeing that there is no other system than the respiratory system which is essentially effected by dust, *qua* dust, the abbreviated term may be allowed to pass as a complete synonym of the word "pneumonoconiosis." I would suggest, further, that to obviate the necessity for coining new words by putting "osis" on the end of every conceivable substance which may produce fibrosis of the lungs, it would appear to be more accurate to describe the condition as coniosis due to the inhalation of such and such a dust. This is almost essential when we consider that dusts are not inhaled in a chemically pure condition, that in some dusts, indeed, the chemical composition is not clearly known—they are mixtures; and above all, that in the course of his employment history one individual may have been exposed to the inhalation of several kinds of dust, each of which is capable of producing fibrosis, and he may at length suffer from a condition due to the cumulative effects of the inhalation of those dusts, and the resulting disease condition could not be represented by a single term signifying one substance.

INDUSTRIES IN WHICH SILICOSIS OCCURS.

Refractories Industries.—First amongst the industries in which silicosis is produced should be mentioned the refractories industries. This group of processes employs some 2,000 to 3,000 persons in this country, and is concerned with the manufacture of ganister and silica bricks for use in metallurgical and other furnaces to resist high temperatures. For this purpose the bricks contain a high proportion of silica, sometimes considerably over 90 per cent. In defining this industry for purposes of compensation under the Compensation Act a restricting term was used, in which the expression "containing 80 per cent. of silica" is used, and by some this has been interpreted as an indication at which a danger line exists for the production of silicosis—in other words, that anything containing over 80 per cent. of silica will produce silicosis and that anything under 80 per cent. will not produce it. This conception is entirely wrong, as the term was used to define the silica-brick industry from the fire-brick industry, and was one of convenience for administration only. The refractories industries were brought by scheme under the Workmen's Compensation (Silicosis) Act in 1919, and by an amending Act certain special medical provisions have been made whereby a specialist medical board carries out periodic medical examinations and examinations for certificates for compensation of all the persons employed. The members of the board are whole-time medical men, with their administrative centre in Sheffield, which is the geographical centre of the industry. The medical board is on lines similar to that of the medical bureau in the goldfields of South Africa. Apart from the administrative value of such a medical board, the members of the present board, Dr. C. L. Sutherland and Dr. S. Bryson, have contributed valuable investigations to the subject of silicosis in industry since their appointment in 1925.

Sandstone Industry.—The sandstone quarrying and dressing industry represents perhaps the most widespread of all silicosis-producing industries. The sandstones include for this purpose the quartzose and quartzite rocks. It must be within the personal knowledge and experience of every one of you that the stonemason working on such rocks inhales almost continuously at his work minute quantities of the dust, and a stonemason's "phthisis" is well known in districts of the country in which sandstone is used as building material. At the present time machining processes are taking the place of much hand work, and as water and mechanical methods of dust suppression can be used, there is likely to be a diminution in the incidence of silicosis. It is still difficult, however, to protect the stonemason who dresses the stone with chisel and mallet. There has been introduced recently a device for the removal of dust from pneumatic hand tools for dressing stone, which is eminently effective. The sandstone quarrying and dressing of sandstone in quarries has now been brought under the provisions of the Workmen's Compensation Act by a scheme of compensation on the same lines as that for the refractories industries.

Granite Industry.—Allied to sandstone quarrying and dressing is the quarrying and dressing of granite. Granite is an igneous rock which consists essentially of quartz, felspar, and mica. In some native granites of this country they occur in about equal proportions. In many igneous rocks, however, the proportion of quartz is much less, or it may be even absent. A study of mortality records indicates that respiratory disease has been produced amongst granite workers to such an extent as to lead inevitably to the conclusion that the dust from granite was an important factor. This is particularly the case in the United States of America, and to a less extent in this country. The subject, however, is complicated because of the varying composition of the rock dealt with. A medical inquiry into the incidence of silicosis amongst granite workers is being conducted jointly by the Home Office and Mines Department at the present time.

Slate Industry.—Reference might also be made to the subject of slate quarrying and dressing. In 1927 reference was made by Dr. Wade of the Welsh Board of Health in a special report on the mortality rate from tuberculosis of the lungs in a slate quarrying and dressing district in North Wales. A medical inquiry was undertaken by the Mines Department, in which clinical and radiological examinations were made of a number of workers in that district. As a result of the inquiry there appeared to be evidence of the production of fibrosis of the lungs, but the occurrence of actual disability within the ordinary working

lifetime of workers was not so clearly shown. It is possible that in this, as in other forms of fibrosis of the lung, tuberculosis may occur frequently and be the cause of death, while the underlying condition of fibrosis may not be easily recognized.

Grinding of Metals.—"Grinders' rot" is a name associated with the Sheffield trades and the manufacture of cutlery and edge tools, where steel implements are ground on wheels of sandstone. This industry has been notoriously associated with the production of silicosis, and especially the combined disease of silicosis with tuberculosis. The death rate in past years was appalling. One has only to consult the literature of the middle of last century to learn how this industry exacted its toll of the lives of those who took part in it. The grinding of metals is also done as a process in engineering and metal working generally throughout the country. The sandstone wheel or grindstone, while still being used to some extent in many of the processes, is being largely replaced by manufactured wheels of abrasives such as carborundum. One effect of this replacement will be the removal of silica dust from the atmosphere and the more easy control of the abrasive dust by the use of water and mechanical exhaust draught. Dry grinding on sandstone wheels is still carried out in certain industries as in the manufacture of textile machinery, but nowadays localized exhaust draught for the removal of dust is so effective that it is a comparatively safe process. The most serious process in this industry is what is known as "racing" the grindstone—that is to say, the truing up of the face of the grindstone when it is first brought into use by the grinder. Formerly, no attempt was made to control the dust, and in the short time necessary to "race" the stone the operator could inhale enormous quantities of dust. These heavy pollutions of the atmosphere, even over such short periods, were enough to produce severe silicosis after the latent period, even without the continuous exposure at the grinding wheel itself. Recent devices have been introduced for removing the dust at this process of racing a grindstone, and with this improvement, combined with the extensive replacement of the grindstone by artificial abrasive wheels, we may look for a reduction at least in the number of cases of silicosis amongst metal grinders. A scheme of compensation has been made for metal grinders under the Workmen's Compensation Act. This scheme is on different lines from those for the refractories and sandstone industries in that it applies substantially the procedure under the Workmen's Compensation Act in regard to scheduled diseases. It provides for payment of benefits only in cases of total disablement and death.

Sandblasting.—Allied to the grinding of metals is the process of sandblasting of metals. This is carried on at metal works, and consists in playing a jet of sand under high pressure against a metal surface to produce certain effects. In some cases the worker is confined in a small room, and he is then protected by a close-fitting helmet with an air feed, much as in the case of a diver under water. In other instances the operator passes his hands into a cabinet, the dust being prevented from escaping from the cabinet by means of air suction. In spite of these precautions and a genuine attempt to maintain the plant in good order, cases of silicosis amongst sandblasters are being met with to-day. It is a process which is becoming more extensively used in industry, and it is a matter for serious consideration whether a substitute, such as iron or steel grit, could not be used to replace the siliceous grit as the abrading material. Sandblasting is also used in the etching of glass.

Pottery Manufacture.—Where does the potter get his silicosis or "potters' asthma"? In the manufacture of earthenware the body of the ware consists of an admixture of clays and ground flint. In the manufacture of china the body contains no ground flint, but ground flint is used to embed the articles of ware while they are being fired in the oven, and also for dusting the surfaces on which the ware may be put when in its wet state. In the case of earthenware, therefore, particles of the body which fall about the benches and floors become dry and are crushed and give off dust which contains free flint. In the case of china, in the process of bedding the china in ground flint and of removing the ground flint after firing, the workers are liable to inhale dust containing flint and thus to contract silicosis. How far the other dusts to which workers are exposed in the manufacture of pottery increase or retard the action of the flint in producing silicosis we cannot say. This is another field in which research is needed. We know that silicosis does occur both amongst earthenware makers and amongst china makers, and in none of the processes in which there is exposure to dust is there absolute freedom of the workers from the risk of contracting silicosis. A scheme of compensation, known as the Various Industries (Silicosis) Scheme, 1929, covers certain workers in potteries, as well as workers in certain other industries and processes laid down in the scheme. These include practically all processes not covered by other compensation schemes where substantial exposure to silica dust occurs.

Crushing and Grinding of Silica, and Industries in which Ground Silica is used.—Ground silica is used in many industries. The silica used is commonly quartz crystal or a highly siliceous quartzite rock. This material is ground fine by machinery, usually dry, and with precautions as to the removal of dust by localized exhaust ventilation. The ground material is placed in sacks and sold in this form. Similar material is also imported into the country from the Continent. Ground silica is used for the manufacture of scouring powders for domestic use, when it is mixed with dry soap powder or alkali or other material, and filled into cartons or packets. It was in this industry that some recent cases of an acute type of silicosis occurred. The evolution of dust is controlled in these processes by the use of mechanical methods of handling, enclosure of machinery, and the use of localized exhaust draught to remove dust or to prevent it from entering into the air of the workroom. Ground silica is used in the manufacture of certain vitreous enamels. It has been used also as a filler in the furniture industry, in the manufacture of insulating materials, and in foundry use. Besides the finely ground silica, flint is sometimes crushed and used in the form of grit for poultry. This crushing process is also accompanied by the evolution of dust, and must be controlled by enclosure of the machinery and removal of the dust by exhaust draught.

Tin-mining in Cornwall has been recognized for many years as an industry with a high mortality rate from tuberculosis, and it has been shown that this was associated with the presence of silicosis. The tin ore occurs in a highly siliceous rock, and in former times drilling of this rock produced much dust, but nowadays drilling is done through hollow steel and with a water feed. Besides the dust in tin-mining itself, a factor in producing this high incidence of silicosis and tuberculosis in the past was the practice amongst tin-miners of working for a time in the gold mines of South Africa, where in former times the amount of silica in the atmosphere was very high and the incidence of silicosis was correspondingly great. Undoubtedly tin-mining in Cornwall can produce silicosis in persons who have not worked outside of this country.

Coal-mining.—Silicosis has been shown to occur amongst workers underground in coal mines. Those affected are the men employed on hard headings, cutting through stone to reach the coal seam. In some cases in which silicosis has occurred the employment on this work has been comparatively short, and it would seem to be the case that once enough silica has been inhaled to produce the nucleus of fibrosis, the resulting inhalation of coal dust into a lung in which the lymphatic drainage has been disorganized has the effect of increasing the fibrosis and producing disability. It seems likely that this type of silicosis is what was classically known as "anthracosis" in the past. We are now aware, however, that coal dust, without any evident exposure to silica dust, may produce a condition in the lungs which radiographically resembles the appearances produced by silicosis.

METHODS FOR DETERMINING THE CONCENTRATION OF DUST IN THE ATMOSPHERE.

A factor of great importance in the production of silicosis is that concerned with the physical properties of the silica, *and especially with the fine state of division.* In sections of a silicotic lung the particles of silica found are, with few exceptions, under 5μ, and a very high percentage of those are under 2μ, the average size of particles being about 1μ. *From what has been said of the etiology of the* disease it is obvious that a fine state of division of silica is necessary to ensure its reaching the ultimate pulmonary tissue. Particles under 2μ in diameter are not visible to the *naked eye in the atmosphere unless present in such* density as to produce cloud effects, and unless particles of this size are associated with the presence of larger particles, or aggregates, which are visible as dust to the naked eye, *it is obvious that the visual appearance of an atmo*sphere is no criterion of its freedom from a dangerous state of dustiness. In investigating the conditions which give rise to silicosis it is necessary to introduce methods for the determination of the concentration of dust in the atmosphere, and several methods of investigating this have been brought into use. The commoner methods may be divided into two classes, depending on the ultimate method of estimation: they are the gravimetric method, and the numerical or counting method.

In the gravimetric method a large measured volume of air is passed through a filtering medium which retains the particulate matter. This is weighed by suitable means and the result calculated in terms of milligrams per cubic metre of air. It is evident that in this method particles of all sizes capable of floating in the atmosphere will be collected, and will be included in the resulting weight, and it follows that the larger particles, which have no pathological significance since they cannot enter the lung tissues, will be represented in the resulting weight in a far higher ratio than the minute particles, which are really injurious, although these are usually infinitely more numerous. The method, therefore, is suitable only for comparing atmospheric conditions as to dust content where the physical state of the dust relative to size is comparable.

The numerical method consists in the collection of the particulate matter from a small sample of air in such a way that it can be examined under the microscope, the particles measured and counted, and, by calculation, the number of particles in a unit volume of air determined. The advantage of this method is that it collects only the comparatively small particles, and by measuring and counting the particles an accurate estimate can be made of the concentration of injurious particles of dust at breathing level in the atmosphere. The drawbacks of the method are, first, only a small and momentary sample can be taken, and this may not be representative where conditions vary widely from time to time; and secondly, the presence in the atmosphere of soot and extraneous matter, which are liable to obscure the particles under investigation and to render counting somewhat difficult.

Both of these methods have been in frequent use in the Factory Department, and in the numerical method of counting Owens's dust-counter has been used. When one is able to estimate concentration of dust in an atmosphere the question arises, Is it possible to establish a standard of air purity within which there is no risk of injury to health? I may say at once that such a standard has not been suggested in this country. To provide such a standard would have certain advantages in that preventive measures for the suppression of dust could be standardized and, by periodic examinations of the atmosphere, such preventive measures could be controlled. The arguments against setting up a standard are, however, strong. In the first place, intensity of air dustiness varies widely, even from moment to moment, in the same process carried on in the same place, and when regard is had to the vast number of processes materially different in character and carried on under widely different conditions, it must be admitted that the factors influencing the results of tests taken in a brief period of time are so great that conclusions drawn from such results are as likely to mislead as to guide. In the second place, it is not known how much silica must be inhaled before the disease is developed. In other words, there is no criterion of air dustiness which we can safely regard as indicating freedom from risk of producing the disease. Each of the various factors has its own weight. The concentration of dust in the atmosphere: the period of time over which exposure takes place; the intermittency of the process; and possibly also the presence of other dusts in the atmosphere, which may have either a restraining or an accelerating effect on the action of the silica itself.

Research is needed before such a criterion can be established. This must include: (1) collection of data regarding the incidence and production of silicosis in the various industries in which it occurs; (2) a study of the influence of other dusts and any modifying circumstances affecting the inhalation of the dust; and (3) the results of preventive measures for the suppression of the dust. These data can only be collected and made effective use of by the concerted action of all those whose work brings them into touch with the sufferers from the disease, and co-operation with the central body whose function it is to investigate and to ameliorate or suppress the conditions under which the disease occurs.

SOME NOTES ON THE BIOPHYSICS OF SILICA AND THE ETIOLOGY OF SILICOSIS.*

BY

PATRICK HEFFERNAN, M.D.,

TUBERCULOSIS OFFICER, DERBYSHIRE COUNTY COUNCIL.

AMONGST the main questions awaiting answers at the *present time regarding silicosis* would appear to be the following:

1. How is the characteristic fibrosis of the lungs which follows the inhalation of fine silica dust, and which is termed "*silicosis,*" *produced?*
2. Are there any factors, apart from prevention of dust inhalation, which hasten, retard, or otherwise modify the development of the condition?
3. Is the fibrosis of the lungs which we speak of as "silicosis" produced by substances other than silica?

In attempting to answer these questions I would suggest that it will help if we review briefly some facts regarding the biophysical behaviour of silica and its use in therapeutics—facts which seem to have a bearing on the points at issue, and not to have received hitherto the attention which their importance merits.

In the *Journal of Biological Chemistry* for November, 1928, Earl J. King published the following table[1] giving the silica content of certain organs of the guinea-pig, rabbit, and dog, and of normal and silicotic lungs in man:

Organ.	Animal.	Mg. of Silica per gram of Organ.		Total in Organ.
		Dry.	Fresh.	
Normal lung	Guinea-pig	0.78	0.12	0.5
,, ...	Rabbit	2.02	0.30	2.53
,, ,, ...	Dog	2.05	0.32	60 72
,, ,, ...	Man	1.40		
Silicotic lung	Man	123.55		
Normal kidney	Rabbit	1.97	0.25	2 95
,, ...	Dog	1.12	0.21	7.23
Normal liver	Rabbit	1.70	0.32	10.50
,, ,,	Dog	1.33	0 34	7. 71
Normal spleen	Dog	0.65	0.16	

One would like to see these figures checked by those of other observers, but, as will be seen later, the evidence of the presence of silica in normal organs is convincing.

The remarkable similarity of the figures for the silica content of the organs of the rabbit, a herbivorous rodent,

* Read in the Section of Occupational Diseases of the Annual Meeting of the British Medical Association, Manchester, 1929.

and of the dog, a carnivore, as shown in the table, is striking. The food of the rabbit, as we shall see presently, contains much more silica than that of the dog. The similarity suggests that the silica content of the organs is independent of the food, and that there is a normal figure for the silica content of animal tissues, differing in the various organs.

The questions may be asked: (1) Does the silica in these tissues subserve a purpose, and, if so, what is it? (2) In what chemical or physical state does the silica exist in the tissues?

To find answers for these questions we need survey a very wide range—nothing less, in fact, than the whole field of biology. In the lowest and least differentiated forms of life we find silica in abundance. The siliceous ectodermal covering—if indeed the term "ectoderm" can be applied to the "skin" of a unicellular organism—of the diatoms forms the great mass of "kieselguhr" which covers great areas of the ocean bed. The diatoms are unicellular algae, whose metabolism is "photosynthetic"—that is to say, they build up their life from air, water, salts, and sunshine. They form the "floating sea meadows," as Sir John Murray called them, which are the basis of all pelagic animal life. If "all flesh is grass," all fish is diatom. It is not a little suggestive that the two basal foods of land and sea animals should be so rich in silica.

In passing, it may be noted that the photosynthetic power of the diatom does not appear to be interfered with by its siliceous coat. Is this Nature's anticipation of quartz glass? There is a resemblance in some respects between the "ectodermal" coat which forms on the surface of the diatom and the envelope which forms round the "micellae" of certain emulsoids—as, for example, in the case of certain kinds of rubber latex—which may be worth bearing in mind.

In the silico-flagellates and the radiolaria we find siliceous deposit within the cell. In one beautiful radiolarian, "Actinomma," there are three concentric siliceous spheres—one in the extracapsular protoplasm, one in the intracapsular protoplasm, and one in the nucleus—joined by radiating siliceous spines.

As we climb up the ladder of plant life we find silica in large quantity in many pteridophytes, such as the equisetums. So great is the silica content of some of the Equisetaceae that the dried plant, made up in little bundles, is sold in Holland and other marshy countries as a scouring material for cleaning kitchen utensils. So far no cases of silicosis have been reported in connexion with this material. As we are all aware, the same cannot be said concerning certain siliceous scouring materials which are manufactured commercially.

Passing on to the spermatophytes, we find silica in abundance. In the Gramineae, for example, the stems and knots of the bamboos, reeds, and cereals, and the hard cutting edges of the coarser grasses, are strengthened with silica, which also largely accounts for the ash of wheat bran, where it abounds in the flaky scales of the fruit coat of the wheat. It may yet be discovered that one of the advantages which brown bread has over white is that it contains more silica.

If we come over to the animal kingdom we find in the siliceous sponges—for there are calcareous sponges also—elaborate skeletons of silica laid down by cells, said to be ectodermal in origin, known as "scleroblasts." The silica is deposited within these cells, round a central organic "thread," and a thin covering of scleroblastic protoplasm is said to cover each spicule, like the "velvet" round a stag's horn, until the full size is attained.[2] After the scleroblast dies the spicule of silica is extruded. The silica in the spicule is opaline, and appears to be laid down in "mesomorphic" or "liquid crystal" formation—that is to say, the molecules are probably arranged in lamellar or concentric formation round the central organic "thread."

It is worth noting that the flints which form beds in our English chalk have been proved in many cases to contain the remains of diatom shells and of siliceous sponges,[3] the opaline silica having been metamorphosed by heat, pressure, etc., into cryptocrystalline flint. Here we have a siliceous homology to the formation of carboniferous limestone.

Among the higher vertebrates, perhaps the greatest concentration of silica is to be found in the quills and feathers of some birds, which contain as much as 40 per cent. of silica by weight.[4]

Further light is thrown on the presence and function of silica in tissues by the more recent work of some German and French investigators. Kobert[5] and Schulz[6] showed, in 1898, that all connective tissues in the body are exceptionally rich in silica. This they found applies especially to the newly formed scar tissue laid down in the healing of pulmonary tuberculosis by "fibrosis." According to Gonnermann,[7] the highest silica concentration in the mammalian organism occurs in embryonic connective tissues. It is high in sinews, tendons, and muscles; fibrin has a special affinity for it; and it is present in milk in considerable quantities—up to 28 mg. per litre—while the iron content, for example, rarely exceeds 1 mg. per litre. In this connexion it is not without interest that one of the most successful of the newer infant foods contains silica in its published formula. Richmond,[8] as well as Bleyer and Callman,[9] confirm Gonnermann regarding the presence of silica in milk.

We may now turn to the more recent developments of the use of silica as a therapeutic agent.

In 1898 Kobert[10] and Schulz[10] were able to show by animal experiments that, with increased silica supply, storage of silica occurred in the lungs. Schulz's work was continued to 1912, and was followed up by Rossle in 1914. This latter experimentalist demonstrated the beneficial effect of silica supply on the healing processes of animals infected with tuberculosis. Kuhn,[10] basing his therapy on the findings of these observers, and upon the work of Zickgraf, Siegfried, Hellwig, and others on the production of leucocytosis by silica supply, introduced his silica treatment of tuberculosis, and published his first series of clinical results in 1920. A further series was published by F. Junker in 1927.[11]

One of the difficulties of silica therapy is the method of administration. Kuhn used a "tea mixture" made from herb galeops, equisetum, and polygonum,[11] which mixture contains silica in the form of alkaline silicates. He later introduced the method of inhalation of atomized water containing colloidal silica sol,[10] which had proved so successful in the treatment of asthma at Mont-Dore, France.

There are grave objections to the "tea mixtures." In the first place, the dose of silica cannot be accurately regulated. Again, all the "teas" are strongly alkaline, and their administration leads to the symptoms of digestive disorder usually associated with the prolonged administration of alkalis. Furthermore, the plant teas contain vegetable alkaloids and other extractives, some of which may be definitely poisonous, as, for example, in the tea made from the equisetum. It is well known that cows and horses fed on "bottom" hay containing a large amount of the equisetum or "horsetail" are sometimes fatally poisoned, the symptoms of poisoning being of the nervous or paralytic type. This poisoning is now attributed by veterinary authorities to an alkaloid called "equisetine." The poisoning has nothing to do with the silica content of the equisetum.

Other siliceous liquids and soluble or miscible substances have, therefore, now replaced "teas" in silica therapy—as, for example, siliceous natural mineral waters such as those of Glashager and Mont-Dore; various colloidal silica solutions, such as those sold under the names of "silistrin," "siliquid," "guasil," "collisil," etc.; the so-called "vegetable silicic acids," said to be "polysilicates of completely unknown constitution and in some cases very labile character" (Zickgraf), such as "mutosan," which contains chlorophyll in addition to silica[10]; and combinations or mixtures of silica with animal or milk albumins, such as "silicasin," which is said to consist of casein 96 per cent., sodium metasilicate 4 per cent., and which forms with water a colloidal solution which is neutral or slightly acid, and thus avoids the evil effects which follow the prolonged administration of alkaline solutions.

According to Zickgraf,[10] silica therapy in pulmonary tuberculosis leads to a fibrous cicatrization of the tuberculous lesions in every way superior to what we know as

calcification by lime salts. He regards the deposition of lime as a sign of degeneration of the tissues rather than as a reparative process. "Lung stones" analysed by him were found to contain silicic acid as well as the preponderating calcareous mass. The evil effects of "demineralization," according to this author, are due rather to a lack of silica than to a lack of calcium. Robin, a French authority, is of the same opinion. According to Rossle and Kahle, cattle and pigs fed on roots which contain little or no silica, as on the German "root crop estates" (Rübengütern), suffer severely from tuberculosis. The disease has been eradicated by the administration of mineral powders containing silicic acid.

According to Gonnermann and Helwig,[10] the administration of silicic acid by the mouth is followed by leucocytosis of very high degree, and Zickgraf maintains that there are two definite physiological actions: (*a*) a fibroplastic action, and (*b*) a leucocytic action.

Kuhn and Zimmer[10] used intravenous injections of silicic acid in arterio-sclerosis, "stenocarditis," and arthritis deformans, and suggested its use in bronchial asthma and diabetes. Zimmer pointed out the danger of overdosing, especially when the intravenous or intramuscular route was used, when symptoms of shock and undesirable secondary reactions of an anaphylactic type were likely to occur. This is not surprising when we consider the effects of intravenous injections of silica hydrosol by Gye and Kettle on rabbits in this country.[12]

The above résumé of some of the literature regarding the place of silica in animal and plant physiology and in therapeutics is, I would submit, conclusive as regards showing that silica is a normal constituent of the human body, and that it is in no proper sense of the word a poisonous substance. Its main function would appear to lie in the strengthening of connective and ectodermal tissues, and in helping in the production of firm scar tissue in healing wounds. In order to function it must enter into the intimate structure of certain cells. In what form does the silica exist in the cell?

Gonnermann, as we have seen, thinks that the silica is present in the form of an organic compound, and Robert wrote, in 1918, that "silicic acid, in a so far incompletely understood organic combination, is a normal constituent not only of all connective tissue, but of all epithelial tissues of the human and animal body." But Mr. J. B. S. Haldane informs me that the only organic combinations of silica described so far, in the case of living organisms, are cholesterol silicate in birds' feathers, and polysaccharide (? cellulose) silicate in plant cell walls. These contain very little silica, which is apparently in a fixed and inert condition, and they appear to be rather the end-products of silica metabolism than active reagents.

When silica is required for skeletal structures it is, to all appearances, laid down as a clear opaline silica, either within the cell, as in radiolaria and sponges, or in the cell wall, as in diatoms and plant cells. Both these methods of deposition strongly suggest that the silica in the cell, before its deposition, exists as a phase of a colloidal system, and not either in true molecular solution or in chemical combination. The silica present in milk is also considered to be in the colloidal state. The modern conception of the colloidal nature of protoplasm, and of the cell as a poly-phase colloidal system, fits in with this conclusion. There seems to be little doubt that the chemistry of the interactions of substances in homogeneous solution can be applied to cellular phenomena only to a limited extent,[13] and that we are much more likely to get some insight into the principles underlying cell metabolism and growth by approaching the subject along the avenue of colloidal physical chemistry than by expecting to find life confining its activities within the bonds of stoichiometric ratios.

It may be asked whether a correlation can be established between the physiological and therapeutical actions of silica, as instanced above, and pulmonary silicosis. The answer would appear to be in the affirmative. According to most clinical observers, a pulmonary fibrosis precedes true silicosis. In the report on the occurrence of silicosis among sandstone workers by Drs. Sutherland and Bryson,[11] published this year, it is seen that "fibrosis of the lungs was diagnosed by clinical examination at an earlier period of employment than that at which silicosis was diagnosed by radiological examination." This was also found to be the case in a similar inquiry into the pottery industry in 1926. This stage would correspond to the condition produced in animals by Kobert and Schulz as long ago as 1898, when they showed that increased silica supply led to storage of silica in the lungs, with consequent increase in the density of the fibrous tissue.[14] From this point of view silicosis is a condition of gross overproduction of fibrous tissue in the lung, which may be due either to the action of comparatively inert silica over a very long time, as in gritstone masons, or to the action of very active silica in a comparatively short time, as in the case of the packers of siliceous scouring powders.

More than a year ago A. T. Green and myself[15] advanced a hypothesis that pulmonary silicosis was brought about by the colloidal activity of fresh silica hydrosol derived from the hydration of quartz dust in the lungs, and not by any poisoning of the cell protoplasm by soluble silica. To some this distinction between a chemical poisoning and a physical adsorption seemed to be rather of academic than of practical interest. To my mind this distinction seems to be of fundamental and practical importance. Let me offer two reasons.

The first is because I believe that the key to certain problems in physiology, pathology, and medicine which are at present baffling us will eventually be found by the study of the physico-chemical or colloidal reactivities of the living cell. Already many specific "tests," reactions, immunizations, and methods of "chemotherapy" are known to be of the nature of "surface" reactions, involving possibly a change in the orientation of the molecule, but not in its composition. Typical examples are the Wassermann test, the suspension stability test, anaphylaxis and its local manifestations, such as asthma. What of that mysterious change in the vital behaviour of a cell which occurs when the cell takes on malignant growth? We know that the prolonged application of such substances as mineral oil, bitumen, tar, and tar-bearing material such as soot, to the skin, particularly if the skin is injured by chronic irritation, will eventually bring about a change in the growth of the subjacent cell from a normal to a malignant form. We also know that if we bring a hydrophobe substance of great surface activity, such as mineral oils or tar, into surface contact with a complex hydrophile polyphase colloidal system such as we believe an active living cell to be, we shall upset the equilibrium of that system. Can we correlate the two phenomena?

My second reason is more directly concerned with the subject of this paper. It is that the colloidal theory of silicosis affords an explanation of the inhibitory or the delaying influence which certain substances, and the accelerative effect which certain other substances, appear to exercise on the development of silicosis, which influences are otherwise inexplicable. The substances which, so far, are believed to delay or inhibit the production of silicosis are carbon and clay. The substances which appear to accelerate the production of silicosis are the alkalis and alkaline soaps.

The evidence in the cases of carbon and clay is partly experimental and partly clinical. It has been fully discussed elsewhere.[16] The evidence in the case of the alkalis and soaps, so far as it is known to me, is as follows. The most rapidly developing cases of silicosis in the literature have been reported in packers of siliceous scouring powders.[17] These powders consist mainly of strongly alkaline dried soap made up with finely ground silica. These products are sometimes described as "abrasive soaps." There seems to be little doubt that the term "adsorbent soap" would be more accurate. All soaps are, of course, to some extent adsorptive in their action. But there is little doubt that the special efficiency of these silica soaps is mainly due, not to abrasive action, but to the adsorptive power of the freshly made silica hydrosol, which comes into existence almost instantaneously when the powders are wetted with water, and which adsorbs the greases, oils, etc., in the well-known selective way for which colloidal silica is rapidly coming into use commercially—for example, the removal or recovery of hydrocarbons, the refining of benzol,

and in the form of silica flour as the best of all bases for adsorbent toilet powders.

The three cases of fatal silicosis reported by Dr. Lennane, Sir Bernard Spilsbury, and Dr. Macdonald, which occurred in girls employed in packing these powders, were beyond all comparison more rapid in their development than any cases of silicosis previously reported. The girls were aged 17, 19, and 23 years at the time of death. These cases had not been published when Mr. Green and I wrote our paper. The confirmatory evidence which they afford in favour of the colloidal theory of silicosis is so strong that it appears to put the correctness of the theory almost beyond doubt, for the combination of alkali and silica in fine subdivision only requires wetting for the immediate production of active silica hydrosol. The solution so formed is not a true solution of a definite chemical individual compound, but is a variable system of sodium oxide, silica, and water, in which, according to Weisser, the ratio of Na_2O to SiO_2 may vary from 1 : 1 to 1 : 4, and the uncombined silica is in the hydrosol state.[18] Hence the colloidal activity of the silica begins immediately the dust has reached the lungs, instead of awaiting the slow hydration of the quartz particles in the pulmonary tissue by the very faintly alkaline tissue juices, as in the case of gritstone masons, quartz crushers, ganister miners, and so on.

The belief that the quartz dust particles are slowly hydrated into silica sol in the lungs is founded mainly upon the experimental work of Gye and Kettle.[12] The latter showed that such hydration occurred when powdered silica was buried in the tissues of guinea-pigs. With a view to comparing this observation with a laboratory test in vitro Mr. Joseph Race, biochemist to the Devonshire Hospital, Buxton, put up a number of substances containing silica (in one case—namely, asbestos—combined silica) in a modified Ringer's solution for eight months. He then decanted off and filtered the fluid, and estimated quantitatively the silica which had been dissolved out. The Ringer's fluid was made up as follows:

Sodium chloride	0.650 per cent.
Potassium chloride	0.014 ,,
Calcium chloride	0.012 ,,
Sodium bicarbonate	0.020 ,,
Monosodium phosphate	0.001 ,,

The reaction was adjusted to give *p*H 7.35 at 38° C. Here are his results:

Material.	Silica found in solution.*
Workshop dust from a silica sand brickworks ...	24
Powdered Yorkshire ganister	28
Commercial asbestos	28
Silicic acid	52
Derbyshire millstone grit (powdered)	52
,, ,, black chert (powdered) ...	55
,, ,, pocket silica sand	60

* Parts per million.

Mr. Race's investigation was done in 1928, and he would naturally wish his figures checked against the work of others before drawing deductions from them. It would be of some interest to note if a slight increase in the alkalinity of the fluid leads to an increase in the dissolved silica. But we may take it that Mr. Race has shown that the slow solution or hydration of silica dust in the lung can be paralleled in vitro with Ringer's fluid.

Among the substances which yielded soluble silica to the Ringer's fluid was asbestos, which is, chemically, a magnesium silicate with sometimes the addition of calcium and a little iron to its molecule. Mr. Race's experiment strongly suggests that "asbestosis" is a true silicosis. A further suggestion is that the "club-moss" growths or bodies found on microscopic examination of the lungs in cases of asbestosis are osmotic silica artefacts, corresponding in type to the "growing plants" of the well-known "silica garden," and are due, like these latter, to surface-tension phenomena limiting the diffusion of the dissolved iron or other salts.

The above constitutes my attempt to answer the questions set at the beginning of this paper. I would beg to sum up as follows.

1. Silicosis is a result of the local action of hydrated silica upon the pulmonary tissue. This action is of a physico-chemical nature, and the speed of its development, other things being equal, depends upon the rapidity with which fresh silica hydrosol is formed and brought into contact with pulmonary tissue.

2. Substances which favour the formation of silica hydrosol from silica, when added to the silica dust, accelerate the development of silicosis—for example, the alkalis. Substances which retard or prevent the formation of hydrosol from silica, or which coagulate the hydrosol when formed, retard or prevent silicosis—for example, carbon, coal dust, clays, and probably many other substances.

3. The action of silica in producing the nodular pulmonary fibrosis which we term "silicosis" has not been paralleled so far by any non-siliceous substance.

4. Silica is a normal constituent of plant and animal cells; its presence seems essential in certain tissues, and its absence from the food of the organism disastrous.

5. The study of the role of silica in biology suggests that many of the processes of cell metabolism belong to the realm of colloidal physics.

6. Some characteristic cellular phenomena are explained most simply by regarding the living cell as a polyphase colloidal system.

7. Silica has a place in therapeutics comparable to that of lime.

METHODS FOR THE REDUCTION OF HUMAN TUBERCULOSIS OF BOVINE ORIGIN.*

BY

WILLIAM G. SAVAGE, M.D., B.Sc.LOND.,

COUNTY MEDICAL OFFICER OF HEALTH, SOMERSET.

THE subject is so large that to cover it adequately it will be necessary for me to deal with parts of it by bald statements of ascertained facts, without giving in detail the evidence upon which these facts and estimates are based. I do so the more readily because this evidence is now obtainable without trouble in my recently published book, *The Prevention of Human Tuberculosis of Bovine Origin*.

THE AMOUNT OF HUMAN TUBERCULOSIS OF BOVINE ORIGIN.

The following table, from the work of a number of English pathologists (F. Griffith, Eastwood, and particularly A. S. Griffith), represents findings up to the end of 1927, as kindly summarized for me by Dr. A. S. Griffith. This represents English results, and the findings from Scottish cases give rather a higher percentage of bovine cases.

Cobbett, using the figures of the Registrar-General for 1915, arrived at the figure of 6 per cent. of all human tuberculosis deaths as of bovine origin. With the 1927 figures my calculations give rather over 5 per cent. bovine. This gives about 1,960 calculated deaths in 1927 as due to the bovine tubercle bacillus in man, the majority of deaths being in children.

* Read in opening a discussion in the Section of Public Health at the Annual Meeting of the British Medical Association, Manchester, 1929.

TABLE.

Variety of Tuberculosis.	No. of Cases	Children under 5 Years.		Children 5-15 Years.		Cases 15 Years. and Over.	
		Human.	Bovine.	Human.	Bovine.	Human	Bovine.

Double portal ...	25	15	0	10	0	—	—
Uncertain... ...	6	2	0	3	0	1	0

* A series of unselected post-mortem tuberculosis cases. Five were cases of mixed infection and are entered twice—that is, as both human and bovine. These are 2 in 0-5 years, 1 in 5-15 years, and 2 in 15 years and over.

A study of the death returns shows, as we know, a marked decline in the death rate from tuberculosis. When we consider respiratory and non-respiratory deaths separately, the decline in the latter group is considerably more in evidence. For example, if we take 1912 as a standard year, respiratory tuberculosis deaths have declined by 22.6 per cent., non-respiratory tuberculous deaths by 48.3 per cent. It is reasonable to deduce a decline in bovine tuberculous infections greater than in tuberculous infections due to the human tubercle bacillus.

Probably not more than 2,000, or possibly 2,300, deaths from human tuberculosis each year are now due to the bovine tubercle bacillus, but we do not know how many infections occur not resulting in death.

THE EXTENT OF BOVINE TUBERCULOSIS.

Since the infections under consideration are entirely derived from tuberculous animals, and, for practical purposes, almost all from the consumption of milk or milk products containing tubercle bacilli, it is unscientific to consider their prevention, or even the reduction of this type of human tuberculosis, without having regard to the extent of tuberculosis in bovines and particularly in cows. Certain particulars may be more or less dogmatically stated. A large proportion of cows are infected with the bovine tubercle bacillus and give a positive reaction to tuberculin. The percentage varies widely in different areas, and is particularly influenced by the age constitution of the herd. Taking the country as a whole, veterinary data indicate that about 40 per cent. are affected.

The great majority of these cows are non-infectious to other animals or to the milk supply, and never become infectious. Others progress and become "open" cases—that is, they shed out tubercle bacilli into their surroundings. There are no reliable statistics as to the percentage of these "open" cases at any one time throughout the herds of Great Britain. A detailed study of the results of routine veterinary inspection of cows in particular areas suggests that cows which can be clinically diagnosed as suffering from tuberculosis are from 0.4 to 0.6 per cent. of the whole. These are all "open" cases, and to these have to be added cows shedding out tubercle bacilli, but unrecognizable by clinical means. At the most we can put the total percentage of "open" cases in herds of cows as not more than 1 per cent., probably less. This is considerably lower than figures often suggested, and is much lower than percentages recorded, for example, in Germany. From the human standpoint the most important type of "open" tuberculosis is that disease affecting the udder, and here a study of detailed inspections suggests 0.3 per cent. as a maximum, and in some areas considerably less.

REDUCTION METHODS NOW IN USE.

Theoretically we might consider separately those measures the aim of which is to reduce bovine tuberculosis, and those the object of which is to reduce the risk of human infection from milk containing tubercle bacilli. The two problems are so interrelated that it is impracticable to consider them apart. We can group the different procedures as follows:

1. *The Elimination of All Tuberculous Cattle.*

By this is meant the testing of all animals with tuberculin and the destruction of those giving a positive reaction, the so-called "reactors." Apart from the fact that a great many of these animals are not infectious and never will become infectious, their wholesale destruction is entirely impracticable. It can be successfully done in small areas —for example, in the Channel Islands. It is also the official plan in the United States of America, and in 1927 as many as 207,830 tuberculous cattle were slaughtered. It is possible in the United States because their percentage of reactors averages 3.3, and in different years only fluctuated between 2.9 and 4.9. It is impracticable in England, with more than ten times as high a percentage of reactors.

2. *Building up Herds Free from Tuberculosis by Selection.*

By making use of the simple procedure advocated by Professor Bang this is theoretically easy. There are, however, many administrative difficulties, and the building up of tuberculosis-free herds along these lines has never been much utilized in this country, and even in Denmark, its original home, its use seems to be declining. This method deserves more employment than it receives. In England the same principle has been followed, but along different lines, and in designated milks we can follow the production of tuberculosis-free herds. Two of the types of these designated milks—that is, Grade A (tuberculin tested), and Certified Milk—are from herds entirely free from tuberculosis, and they are able to advertise this fact.

Their growth has been of the slowest, and after six years' working there were only 152 "Certified" Milk and 207 Grade A (tuberculin tested) producers at the end of September, 1928. This, of course, is an entirely insignificant proportion of producers. In Somerset, with at least 7,300 producers, there were only eleven producers of these two types of milk at the end of 1928. As a practical solution of our problem these two types of milk can be neglected. Apart from these designated herds there are a good many herds the owners of which maintain them free from tuberculosis by careful selection, repeated testing, etc.

3. *The Elimination of Particular Classes of Tuberculous Cows.*

On theoretical grounds it is a sound policy to eliminate all infectious cows and so reduce both the spread of infection to bovines and the risks of tubercle bacilli in the milk supply. This is the aim of two separate procedures—the Tuberculosis Order, 1925, and routine veterinary inspection of dairy cattle. Under the Tuberculosis Order three types of bovines have to be reported, and, if the diagnosis is confirmed, destroyed, compensation being payable. For practical purposes these types correspond to "open" cases of tuberculosis. If these animals were all reported, or could all be reported, so soon as they became "open" cases, and if the disinfection and other steps in the Order were efficiently carried out, it is evident that this procedure could be an efficient weapon to reduce bovine tuberculosis and to protect the milk supply. In fact, however, partly from administrative defects, but mainly from scientific difficulties which are only removable to a limited extent, these desirable objects are not being attained. For example, these "open" cases are only being notified and destroyed so long after they have become infectious that most of the harm they are capable of doing has been done before they are destroyed. The finding of these cases

is not being followed up by a systematic examination of the other animals. Of particular importance from the human standpoint, cases of tuberculosis of the udder are not being detected, or are only reported when the disease is advanced and the milk supply has been affected for long periods before detection.

A scheme of systematic veterinary inspection of dairy cattle is legally in force in Scotland, is permissive in England, and is being carried out in a few areas. The scheme is being stressed by most members of the veterinary profession as the one urgent method by which to tackle these problems. It is an advance on the methods in the Tuberculosis Order, in that under the Order the cow-owner is instructed to report conditions which he has not the knowledge to detect, so that only the advanced cases are reported. Under this scheme the expert will go to the cowsheds and himself detect these infectious animals, so that theoretically the elimination of "open" cases will be prompt, thorough, and complete.

Unfortunately there are serious difficulties in the way of obtaining these theoretical results. The first is the inability of even the ablest veterinary inspector to detect these infectious animals in their early stages. Also these pathological conditions may advance in the cow with considerable rapidity, so that fairly frequent inspection is necessary. Financial and staff considerations limit severely the frequency of inspection. The wider the interval between the inspections the greater the number of animals which in the meanwhile will have developed open lesions and be a source of infection before their recognition. Dairy herds are unstable combinations, and additions and abstractions from the herds are constantly taking place. Veterinary inspection at its best under practical conditions can only hope to remove the comparatively gross cases of infective animals.

This raises the supremely important point as to the susceptibility of the cow to tuberculous infections. I emphasize its importance because in my opinion the administrative validity of any scheme of veterinary inspection of cows turns upon this question. In man there is evidence of some reliability that removal of cases of advanced tuberculosis diminishes the intensity of infection amongst contacts. With the physiologically overworked cow, subjected to the heavy strain of frequent calf-rearing, and so often kept under grossly insanitary conditions, the same may not be true. Put quite simply, routine veterinary inspection of our cattle will remove gross cases of tuberculosis, but will not remove all sources of infection. Will the removal of such infectious sources as it can effect play any decisive part in reducing the amount of bovine tuberculosis? The figures that we have from places where routine inspection has been in vogue for years do not show any such reduction.

Clearly this procedure can only reduce very partially, not remove, the risk of tubercle bacilli in the milk supply, and for that degree of reduction alone it is not worth the heavy expense entailed. I calculate the cost of a reasonably adequate system of veterinary inspection as rather over £300,000 a year, while it would press heavily in individual areas—for example, in Somerset it would cost about £13,500 a year.

I consider that this procedure must stand or fall on its merits as a means of reducing *bovine* tuberculosis. If it can be shown to accomplish this, and so reduce tuberculosis in bovines year by year to manageable proportions, it is a true preventive measure and thoroughly worth the price. I suggest to my veterinary friends that the onus is on them to demonstrate its ability to reduce bovine tuberculosis. Up to the present they do not even consider this point, for at the important discussions in June, 1928, at the World's Dairy Congress, not a single one of the distinguished veterinary surgeons discussing this matter paid the slightest attention to this problem, although it was discussed from almost every other angle.

4. *Measures Directly Aimed at Reducing the Amount of Tubercle Bacilli in Milk.*

These are of two kinds—bacteriological milk examinations and heat treatment of the milk. Although extensively employed and of considerable utility the value of bacteriological examinations is almost entirely educational; they do nothing effective to protect the milk supply of any particular community. Take, for example, any town or city, it is only possible to bacteriologically test a quite insignificant proportion of the milk supply. When tubercle bacilli are detected it is feasible in something like 60 per cent. of the cases to find an infective animal and eliminate her. Clearly that amounts to nothing as regards protection of the milk supply. It is a system of spot sampling, such as we use for chemical milk testing. Spot sampling for chemical purity is effective, because a proved deficiency constitutes a statutory offence and fear of publicity and a penalty is the deterrent. When tuberculosis is found there is no penalty, but, on the contrary, public money is freely spent to provide free veterinary assistance and additional bacteriological examinations, while compensation is paid when the tuberculous cow is detected.

Pasteurization of the milk supply is along an entirely different line. In effect it assumes that none of our existing measures give us adequate protection from the risk of consuming tuberculous milk, and the only way we can achieve that protection is by heat treatment to eliminate the risk of their presence. It is impossible for me, in my limited time, to cover the large question of pasteurization. All I wish to say is that I am prepared to agree that, as carried out in the laboratory, pasteurization will very largely eliminate the dangers of tuberculous milk. Between laboratory results and a practical efficient working system there is a wide gulf, which, however, can be bridged. I do not think its opponents have demonstrated that, when efficiently performed, it does any material damage to any known nutritional qualities of milk, but there remains the possibility that it may destroy other valuable properties at present unknown. There are very considerable objections to a compulsory system of pasteurization on other grounds related to the various problems of clean milk, and if we have to adopt it as the best available method of protection from tuberculous milk I should regard it as a confession of failure, and the acceptance of a second best procedure, only to be adopted with very adequate precautions.

5. *Immunization of Cows against Tuberculosis.*

Theoretically practical, this method still remains experimental. Calmette's B.C.G. vaccine is on trial and should be very fully tested, but later results are not very favourable. It is a short cut to a solution of this difficult problem, and we can only hope it will not share the failure of all other short cuts for the treatment of tuberculosis.

Suggestions as to Lines of Reduction to Adopt.

In the above account I have aimed at a summary of the rather bewildering number of remedies advocated, or utilized, to deal with this complicated problem. We can say at once that all methods specifically aimed at preventing tubercle bacilli from gaining access to milk are only palliatives, and not true preventive measures, in that they do nothing to reduce the need for their continuance by reducing bovine tuberculosis. Admittedly the operation of such measures as the Tuberculosis Order, or a scheme of veterinary inspection of cows, will effect some reduction in the risk of tuberculous milk. Administratively the question is whether this reduction is worth the price to be paid for it if such measures do not also effectively reduce tuberculosis in bovines. If we could be sure of two things—that is, that the risk of all *gross* infection with tubercle bacilli is removed by these measures and that only gross human infection matters—there would be a great deal to be said for their utility, but, as has been shown, they do not remove all gross infection or anything like it, while our pathologists are not in a position to assure us that moderate infections by way of the tonsils, etc., are negligible.

I consider that the value of these measures really turns upon their efficiency as agents for the reduction of bovine tuberculosis. Taking the long view, I suggest that the real problem is one of the reduction of bovine tuberculosis. Tuberculosis in dairy cattle has never received adequate consideration on broad preventive lines, but has been dealt with by the application of special procedures of limited scope, which fail, and, in my opinion, must fail,

because they are not part of a broad comprehensive scheme. Abundant illustrations might be given, but taking the latest of the remedies advanced—the routine veterinary inspection of dairy cattle—it is advocated as a thing worth introducing by itself, or to protect the milk supply, and never with a realization of the need to fit it into a wide comprehensive scheme. By itself I regard it as not worth doing, but it occupies quite a different place as part of a comprehensive attack on bovine tuberculosis.

As part of such a comprehensive scheme certain changes seem to me to be essential requirements. One is a radical alteration in the environmental conditions of the cow. There seems no reason that the agriculturists have advanced why the usual practice of keeping cows all the winter in insanitary cowsheds should not largely give place to their living under much more open-air conditions, the sheds possibly being used for milking or housing under exceptionally severe conditions.

A second step is the development of adequate measures to prevent or at least limit the spread of infection. The partial abolition of the cowshed will materially reduce risks of infection, but, in addition, more direct measures are necessary. One is a more active educational campaign. A second is to place part of the onus of preventing infection upon the cow-keeper. Since a material part of the cost of bovine tuberculosis now falls upon the central and local public health authorities, it is but logical they should have some powers to limit their expenditure by insisting that cow-owners should exercise due precautions to prevent infection. Cow-keepers who, by wilful failure to take due precautions, add to the nation's bill for tuberculosis should be penalized.

Problems of feeding and other factors affecting tuberculosis in cows all merit careful consideration in any well-thought-out programme.

Into such a scheme can profitably be fitted immunization experiments, the formation of tuberculin-free herds, the operation of a modified Tuberculosis Order, the routine veterinary inspection of cows, etc. Veterinary inspection of cows would be most valuable as part of such a scheme and might be made a most helpful procedure.

It will be noted that in any such scheme I give a prominent place to the active co-operation of the cow-owner, and regard that as essential. Any comprehensive attack on bovine tuberculosis is ultimately for the benefit of the farmer and the stock-owner. The present measures, in use or advocated, whereby a great deal of public money is spent on an attempt to diminish bovine tuberculosis without insisting on his active co-operation, are not only illogical but, in my opinion, likely to effect comparatively little. Considerable financial assistance to the farmer is necessary, since the difficulties of eradication are so considerable, and no one who appreciates these difficulties would wish to reduce the assistance or belittle its need. At the same time it is logical to ask that, as some return for that assistance, there should be a very active co-operation on the part of the stock-owner.

While such a scheme has as its primary aim and object the reduction of bovine tuberculosis, *incidentally* it would do a great deal to reduce the dangers of milk being infected with tubercle bacilli. This particularly applies to certain parts of it, such as routine veterinary inspection of dairy cattle, if bacteriology is adequately utilized in connexion with such inspection.

If the agricultural community decides that it is not prepared to co-operate actively (for that is what it amounts to) in the measures of the State and of local authorities to reduce the incidence of bovine tuberculosis; that, while willing to receive rate-aided assistance, tuberculosis is not of sufficient moment to agriculture to warrant the considerable disturbances to existing practice which are required, then another line of procedure is necessary. In that event I do not think it worth while, for the small measure of reduction of human tuberculosis which will accrue, to continue these partial measures, such as the Tuberculosis Order, an inadequate system of veterinary inspection, or occasional milk sampling for the tubercle bacillus. The extent of their success is not likely to be commensurate with their cost—at least, as regards the human side of the problem. It is better for those concerned with the human infection side to face their own problem in their own way: to leave bovine tuberculosis to those concerned with animal diseases, and to protect the milk supply by an efficient and adequately controlled system of pasteurization. It is a confession of failure, the second best instead of the best. It has extensive drawbacks, and cannot be advocated without combination with other procedures, the aim of which is to minimize these drawbacks as far as possible.

In view of these drawbacks and other inherent objections to pasteurization, I greatly prefer the adoption of the preventive measures indicated to deal with bovine tuberculosis, but if these are not attainable, pasteurization seems less of an evil than the present tinkering procedures. Pasteurization will give a more effective protection to the milk supply than any incomplete scheme under existing conditions.

A CLINICAL STUDY OF ACUTE RHEUMATISM.

BASED ON WORK AT THE RHEUMATISM SUPERVISORY CENTRE, ROYAL BOROUGH OF KENSINGTON.

BY

R. C. LIGHTWOOD, M.D., M.R.C.P., D.P.H.,

ASSISTANT PHYSICIAN, PRINCESS LOUISE KENSINGTON HOSPITAL FOR CHILDREN AND SOUTH-EASTERN HOSPITAL FOR CHILDREN; CHIEF ASSISTANT TO THE CHILDREN'S DEPARTMENT, KING'S COLLEGE HOSPITAL;

AND

M. LLEWELYN DAVIES, M.B., B.S.,*

LATE ASSISTANT PHYSICIAN TO THE KENSINGTON RHEUMATISM SUPERVISORY CENTRE.

JUVENILE rheumatism is a disease characterized by its protean manifestations, its tendency to relapses, and its proneness to attack the heart. The aim of a rheumatism supervisory centre would be, were it possible, the prevention of rheumatic disease of the heart. Unfortunately the physician's hands are tied by ignorance of the exact cause of rheumatism, by possessing no specific remedy for its cure, and by having no sure or ready means for protecting the heart from its attacks. It has been said that the prevention of rheumatic heart disease can only be attained when rheumatism itself can be prevented, and, while we are not able, with our present knowledge, to prevent either rheumatism or rheumatic involvement of the heart, yet there is good reason to believe that relapses may be avoided by the employment of certain preventive measures. Put briefly, these measures consist in providing for the rheumatic child management and surroundings as near the ideal as possible, remembering that he cannot be neglected without risking exacerbations.[1] When the heart is already affected careful supervision may do much to enable the child to attain a degree of physical fitness sufficient to enable a return to a normal occupation. Thus the primary object of a rheumatism supervisory centre is twofold: the prevention of relapses and the after-care of those children whose hearts are already involved. In the latter group of children these two objects are inseparable; the best guarantee that a damaged heart will make a satisfactory recovery being to ensure that no further bouts of rheumatism occur, maintaining during the healing stage of rheumatic heart disease a careful supervision of all physical exertion.

With these principles in mind we decided that the functions of the rheumatism supervisory centre† should be: first, to make use of all the measures available for preventing relapses in rheumatic children, and, secondly, to supervise the after-care of children already the victims of rheumatic heart disease. Not directly related to either of these functions, but rather in the hope of adding something, however little it might be, to the knowledge of rheumatism, we have, by keeping careful records of the cases, been investigating juvenile rheumatism along clinical lines.

Prevention of Relapses.

The lines on which recurrences of rheumatism may best be prevented are: (1) correction of unsuitable environmental conditions; (2) attention to general health; (3)

* Working with a grant from the Medical Research Council.

† Established in connexion with the rheumatism scheme of the Royal Borough of Kensington.

treatment of diseased tonsils; (4) education of the parent in the correct management of the rheumatic child. The correction of faulty home conditions being for the most part impossible, removal of the child from its home environment to more suitable surroundings is a measure on which much reliance is placed by us and by all other workers in the field of juvenile rheumatism. But while our main attack on faulty environment has been the provision of convalescent treatment for the mild cases, and, for the severe ones, the use of certain residential institutions, let it not be forgotten that this method of temporary removal is chosen because it is the line of least resistance, and not because it appears to us to be economically sound. Apart from this temporary removal to better surroundings, something is being attempted to improve the surroundings and management of these children when they return to their homes in Kensington. The Invalid Children's Aid Association visits the homes of all rheumatic children, giving instruction and advice to the mothers. In many cases housing defects are remedied through the activities of the public health department.

Work of the Centre.

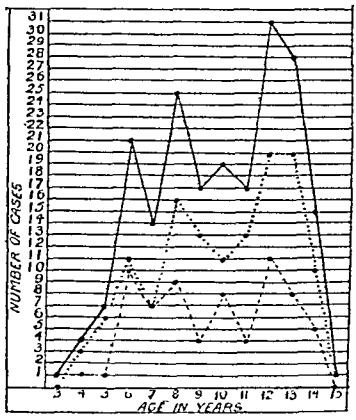
In dealing with each rheumatic child there is an important practical point for the physician to decide—namely, whether the disease is in an *active* or a *quiescent* stage. No arbitrary definition of activity has been adopted by us, each case being judged on its merits, but we have frequently experienced difficulty in deciding whether a case is to be regarded as active or not. *Active* rheumatism requires thorough and sustained treatment, and we regard it as the duty of the centre to see that proper treatment is carried out. Where the family are in a position to call in a private doctor this is the course which is recommended; otherwise the patients have been admitted to various hospitals. When the disease is found to be *quiescent* it has been our practice to re-examine the child at appropriate intervals, appointments being arranged at the centre for this purpose. Many of the quiescent cases, and certain cases of subacute rheumatism without cardiac involvement, benefit considerably by short periods of convalescence in the country or at the seaside. For some of the older children who suffer from relapsing rheumatism, or in whom there has been sufficient cardiac damage to render them unsuited to the rough and tumble of an ordinary London County Council school, we have found the special schools for physically defective children to be invaluable.

Allocation of Cases to the Rheumatic Group.

The following observations are based on a statistical study of the first 200 patients attending at the centre. In our series we have included only children in whom we were satisfied that rheumatism was, or had been, present. The difficulty in diagnosing the milder grades of rheumatism was experienced by us, as by others, and each of our cases had to be considered on its merits. There was seldom much difficulty in the diagnosis of chorea; occasionally at the first visit a mild case might be puzzling, though subsequent observations always enabled us to make a definite diagnosis. Four cases of habit spasm had to be excluded; it is of interest that all these had been notified as suffering from chorea. We came across cases of habit spasm among the rheumatic children, though not more commonly than among the ordinary out-patients of a children's hospital, and we did not regard this disorder as a symptom of rheumatism or as being related to it. Erythema nodosum was excluded because, in our opinion, this disease is not a rheumatic manifestation; others excluded were such widely differing conditions as traumatic synovitis, flat-foot, vasomotor disturbances, cyclical vomiting, and hypothyroidism. Some cases of aches and pains in the limbs were excluded, either because they had occurred on only one occasion or because the symptoms could be adequately explained on other grounds. On the other hand, we included patients in whom limb pains recurred persistently for weeks and months if no explanation other than rheumatism was forthcoming, even though no other rheumatic manifestation might be present. No doubt there are cases in our series which some would be disinclined to regard as rheumatism. Often in cases where the diagnosis presented difficulty, help was subsequently obtained by our finding a slightly dilated heart, or a systolic bruit, or by the patient developing an obvious rheumatic exacerbation. The rest of the cases include children with more than one manifestation of rheumatism, or with one definite manifestation such as chorea or mitral stenosis. In accepting patients in whom the physical signs were the chief or only evidence of rheumatism every effort was made to exclude congenital morbus cordis.

Age and Sex.

The rheumatic scheme of the Royal Borough of Kensington concerns itself only with children under the age of 16 years. The youngest child in the series was aged 3 years and the oldest 15 years. The ages of the rheumatic



Continuous line = sexes combined. Dotted line = females only. Broken line = males only.

children when they first presented themselves at the centre are shown in the accompanying graph.

It will be seen that the highest age peak occurs at 12 years, with lesser peaks at 6 and 8. When the sexes are plotted separately it is seen that at all ages the females preponderate (131 to 69), but the males contribute relatively more in the age group 5 to 8 and relatively less in that of 11 to 13 years.

Cardiac Involvement.

Examination of the hearts of the 200 children in the series, repeated as often as they attended the centre, showed that 35 (17.5 per cent.) had definite rheumatic heart disease; the hearts of 6 of these children appeared to get worse during the period they were under observation; one has died of malignant endocarditis. No heart in this group was observed to get appreciably better, and the majority remained unaltered. The period of observation, however—three to eighteen months—was short. In 108 (54 per cent.) of the children the heart was normal when they first presented themselves, but in 4 of these the heart subsequently became involved; a fifth child developed acute pericarditis, which cleared up, and six months later (when the child was last examined) had left no trace of heart disease. The remaining 57 children (28.5 per cent.) were placed in the category of "doubtful hearts." For the most part the physical signs in this group were those of slight or moderate dilatation, reduplication of the second mitral sound, premature systoles, and simple tachycardia—abnormal physical signs which might later disappear without leaving any trace. Subsequent observations showed that 12 patients in this group had improved and one had got worse.

The State of the Heart and Tonsillectomy.

A study of the relation between the state of the heart and tonsillectomy yielded the following data. In 115 patients who had never been subjected to tonsillectomy the heart was normal in 64, doubtful in 29, and diseased in 22. In 40 subjected to complete tonsillectomy the heart was

normal in 23, doubtful in 10, and diseased in 7. In 45 who had had incomplete tonsillectomy the heart was normal in 21, doubtful in 18, and diseased in 6. These data give no indication of the relation between the date of tonsillectomy and that of cardiac involvement; indeed, the date of the first attack on the heart can seldom be obtained with any degree of accuracy, and frequently it is quite unknown. With such a high proportion of doubtful hearts we did not feel justified in drawing conclusions from the data before us, especially as the throat operations might have been performed either before or after the cardiac damage had taken place. Leaving doubtful hearts out of account, it seems that the ratio of diseased hearts to healthy hearts in each of the three groups is approximately the same, a slight difference in favour of the operated groups being too small to be significant. One important fact may, however, be gleaned from the figures; of 85 tonsillectomized children no fewer than 45 (53 per cent.) had suffered incomplete removal of the tonsils. Now unless it be argued that incomplete removal of tonsils predisposes towards rheumatism, the results in this series, as far as the completeness of tonsillectomy is concerned, may be taken as representative of those obtained in various London institutions. Other workers have drawn attention to the high proportion of failures in tonsillectomy, and we do not propose to deal further with this question than to remark that the guillotine operation can be relied upon to give uniformly satisfactory results only in skilled and practised hands.

Onset of Rheumatism and Date of Tonsillectomy.

The relation between tonsillectomy and rheumatism in our series was further studied by ascertaining the time relation between the onset of rheumatism and the date of tonsillectomy in the group of 85 tonsillectomized children. The data are tabulated below.

TABLE I.	Cases.
Rheumatism began before tonsillectomy	40
Rheumatism began after a complete tonsillectomy	10
Rheumatism began after an incomplete tonsillectomy	27
Doubtful. The history did not clearly indicate whether rheumatism preceded or followed tonsillectomy	8
	85

Though the cases are few in number it would appear that, as compared with the children with tonsillar remnants, the tonsillectomized children have a relatively small liability to contract rheumatic infection.

Rheumatism following Tonsillectomy.

Dr. Reginald Miller[2] has suggested that although tonsillectomy does not prevent rheumatism, it modifies its virulence, making the appearance of heart disease uncommon in tonsillectomized children. The figures just cited show that in our series there were 37 children in whom rheumatism began after partial or complete tonsillectomy. We analysed the rheumatic manifestations occurring in these children, and the figures we obtained lend support to Dr. Miller's view.

TABLE II.—*Tonsillectomy before Onset of Rheumatism.*

	Complete.	Incomplete.
Pains only	5	14
Chorea only	1	0
Pains and chorea	2	1
Pains and/or chorea with heart disease	2	12
	10	27

It is significant that in our series of 200 rheumatic children—of whom 40 had been subjected to complete and 45 to incomplete tonsillectomy—only two children could be shown to have developed heart disease after complete tonsillectomy.

Dental Caries and Constipation.

Observations on the presence of dental caries were made in 154 cases; of these, no carious teeth were present in 97; one carious tooth each in 29; two carious teeth each in 9; three or more carious teeth each in 19. For comparison we may refer to Dr. Livingston's report[3] on the Michael Faraday School (Walworth). In 1927 he found that only 21.5 per cent. of the children were completely free from dental caries. The figures of the School Medical Service[4] showed that among 2,213,721 children inspected the incidence of dental disease was 63.9 per cent. We have formed the opinion that the teeth of the rheumatic children in our series compare favourably with those of children seen in the out-patient departments of children's hospitals. Other workers on rheumatism have arrived at a similar conclusion, and there seems to be no evidence of an association between rheumatism and dental caries.

The rheumatic child has been described as a constipated child. With a view to clearing our minds on this subject we took notes of 152 cases, and found that constipation was relatively infrequent, occurring in only 17 children (11 per cent.).

Cardiac Irregularities.

All the cardiac irregularities noted fell into one or other of two groups: (1) sinus arrhythmia; (2) premature beats.

Sinus Arrhythmia.—The observations on sinus arrhythmia were made with the patient in the prone position. The effect of deep breathing on the arrhythmia was always noted before the presence or absence of sinus arrhythmia was recorded; 87 children were examined, sinus arrhythmia being present in 66 (76 per cent.) and absent in 21 (24 per cent.). Of those in whom sinus arrhythmia was present, 16 (24.2 per cent.) were classified as cases of active rheumatism, while of those in whom it was absent 10 (47.6 per cent.) were so classified. Sinus arrhythmia may be present or absent in children with active or quiescent rheumatism, just as it may be present or absent in healthy children. Our observations suggest, however, that though marked sinus arrhythmia is the rule in chorea (always classified as active rheumatism in our series) it is more often absent in the active rheumatic cases than in the quiescent ones. Active rheumatism is usually associated with a rise of pulse rate, and the fact that tachycardia tends to banish sinus arrhythmia probably accounts for its relative infrequency in active rheumatism. The presence of exaggerated sinus arrhythmia in the rapid heart of chorea is interesting; it may be connected in some way with the sympathetic and vagal disturbances of the condition.

Premature Beats.—Although we were on the look-out for this irregularity we found it in only 3 cases (1.5 per cent.). Extra-systoles are uncommon in the hearts of rheumatic children; in the normal child they are even more rare. We regard them as an indication of inflammatory (or possibly toxic) involvement of the myocardium. Details of the three cases are as follows:

Case 1.—A girl, aged 13, was seen in a first attack of chorea, and admitted to Princess Louise Hospital for Children. Pain had occurred in various joints for two weeks before admission. When the patient was first examined premature beats were occurring frequently and considerably upsetting the cardiac rhythm; a well-marked sinus arrhythmia further complicated the rhythm. During her stay of two months in hospital premature beats were usually to be heard, and were not banished when she held her breath. On her discharge to a convalescent home a localized mitral systolic bruit was to be heard. After eight months the extra-systoles and the systolic bruit were still present.

Case 2.—A boy, aged 11, had developed rheumatism at the age of 6, and chorea at 9½. At the first examination there was no evidence of heart disease, but later extra-systoles were usually to be heard. He has been observed for a period of fifteen months and extra-systoles are still occurring. No other manifestation of cardiac involvement has appeared, but rheumatic pains continue.

Case 3.—A girl, aged 7½, developed rheumatism at the age of 4 years. When first examined she had a gross cardiac irregularity, due to frequent extra-systoles. There was a mitral systolic bruit. An electro-cardiogram confirmed the clinical findings, and showed that the premature beats were arising in the auricle. After three months' observation coupled beating, due to extra-systoles, was heard. Two weeks later this observation was repeated. Some five months later the following was recorded: "Frequent premature beats—often coupled beating for about twenty beats at a time. Premature beats present when breath is held in full inspiration." After a total observation period of over sixteen months the extra-systoles are still occurring and the mitral murmur persists.

Rheumatic Tachycardia.—A high pulse rate is the rule in active rheumatic infection; some rheumatic children, however, show a degree of tachycardia which is out of

proportion to the severity of their affection, and fall into a clinical group called "rheumatic tachycardia." There were 6 (3 per cent.) such cases in our series. Their characteristic symptom is sustained rapidity of the heart, which is not affected to any extent by treatment, whether this be rest in the prone position, sedatives, salicylates, or digitalis. It is possible that the tachycardia is less an indication of myocardial involvement than of a derangement of the nervous control of the sino-auricular node, for we have been surprised at the unexpectedly benign course of these cases, and, unless there is evidence of valvular or myocardial damage apart from the tachycardia, we take an optimistic view about them. Subsequent damage to the valves has not occurred in our cases during the period they have been under our care, but further observation will be maintained.

Incidence of Exanthemata.

There was a history of the various exanthemata in approximately the expected proportion of the children. Measles, the most frequent, had occurred in 88 per cent. of 189 children; diphtheria (16 per cent. of 190), and scarlet fever (15 per cent. of 189) were the least frequent. A history of rheumatism beginning after attacks of measles, diphtheria, and scarlet fever was obtained in various cases, and though it is possible that in a disease as common as rheumatism coincidence may be a sufficient explanation, the debilitating effect of the exanthemata must not be overlooked.

THE SURGERY OF ACCESS TO THE PLEURAL CAVITY.

WITH ILLUSTRATIVE CASES.

BY

E. R. FLINT, F.R.C.S.ENG.,

SENIOR ASSISTANT SURGEON TO THE GENERAL INFIRMARY AT LEEDS.

THE three cases in this paper are reported in order to show that the pleural cavity of one side may be freely opened with impunity under the ordinary arrangements of general anaesthesia. The opening made is large enough to see and feel the whole of the contents easily. This is not a new observation; I learned the lesson in the war whilst removing shrapnel and bullets from the lung. Those patients were all young men, and it was usually possible to reflect and subsequently replace a rib. Two of the patients whose cases are reported here were over 60; their ribs were brittle and were removed, as they fractured during the process of elevation. I was not sure what would be the effect on the circulation and respiration of widely opening the pleura at this age; apparently this was no more disturbing than in the younger men, and that is to say nothing beyond a little quickening of both pulse and respiration, which gave rise to no anxiety whatever. There were no adhesions to separate, and so no bleeding, and there was no infection. It was a combination of these two things in the war cases which sometimes caused the development of an empyema, for the foreign body was almost always infected in some degree, and adhesions were cohesions and extensive.

Surgery has still to find its legitimate place in dealing with conditions in the chest. Widely opening the pleura in the presence of a suppurative lesion in the lung is often made difficult by adhesions, and must of necessity put the patient to the grave risk of an empyema. In some degree in such an operation as lobectomy—for example, in carcinoma of the lung—the same risk is run by infection from the bronchi. At the best it is only rarely, and then in specially selected cases, that this line of treatment is possible, though experience may show us that the present limitations may be exceeded. However, it is as a means of access for radium applications that I wish particularly to use these three cases as illustrations. It may happen from time to time that a radium needle inserted for carcinoma of the breast will work through into the chest, as happened in the third of these three cases, and it is comforting to know that it may be recovered without any undue risk to the patient; but the radium applications to which I particularly want to allude are in cases of primary carcinoma within the chest, and especially of the lung.

I have seen no reports of any work being done on these lines, but it seems to me well worth giving the method a trial when the opportunity arises. The large opening in the pleura with its attendant complete collapse of the lung—so dreaded in the past—would be a great advantage, for it would enable the growth to be palpated with ease, and the access afforded would allow of the application of the radium needles with precision. Adhesions, if present in this disease, are not particularly baffling, and so the separation of them would be unlikely to be attended with troublesome haemorrhage, and the risk of infection would only be that of any other "clean" operation. It is up to the physicians, who see these cases, to take the initiative; a reasonable proposition of this kind should be welcomed by them, for the mortality at present is 100 per cent.

CASE I.

The patient was a man, aged 65. A lump had been noticed on the chest wall of the right side for six months. During this time it had steadily increased in size. There was no pain. He was seen by me in April, 1928, when the tumour was about the size of a duck's egg and fixed to the sixth rib in the anterior axillary line. The tumour was hard, rather elastic, and nodular. No abnormal signs were detected in the chest. A diagnosis of chondromyxosarcoma was made. On April 18th, 1928, the tumour was exposed and found fixed to the sixth rib; this bone was divided an inch beyond the growth at both ends, and it was then found that there was a mass projecting into the pleural cavity, covered with pleura, of course, but intimately adherent to it. The mass of growth on the inner side of the chest wall was slightly larger than the part projecting beneath the skin. The pleura was opened and the adherent part cut away with the growth. On opening the pleura the lung collapsed at once and completely, but this did not appear to inconvenience the patient in the least. After removing the piece of rib with the growth and adherent pleura a hole in the pleura was left through which one's hand could pass easily, and it was found impossible to close the gap except by drawing together the split pectoral muscles.

The patient made a perfectly smooth recovery, and within a week the lung appeared to be fully expanded. Sixteen months later the patient does not present any evidence of local recurrence.

Microscopic examination of the tumour proved it to be a chondromyxosarcoma of very malignant aspect, showing numerous mitotic figures and great irregularity of cell structure.

CASE II.

A woman, aged 63, who had had her right breast removed for carcinoma—verified by histology—noticed, five years later, a small nodule over the sterno-clavicular joint region, which gradually increased in size. There was very little pain. She was seen by me in May, 1928. There was a hard, ill-defined tumour at the inner end of the first intercostal space on the right side; this was obviously a recurrence, and was firmly fixed to the bone. There was no cough or other sign to suggest intrathoracic extension.

On May 6th, 1928, I removed a part of the clavicle and the inner ends of the first and second ribs, together with the growth, which was adherent to the pleura; extending outwards from the adherent part a few plaques of hard growth were seen reaching away to about one inch beyond the point of adhesion. The pleural cavity was opened and the involved pleura removed with the rest of the growth. The lung collapsed, causing no obvious inconvenience to the patient, and she made an uninterrupted recovery. There was no evidence of recurrence a year later. Histologically the tumour was proved to be carcinoma.

CASE III.

A woman, aged 46, was admitted to hospital recently with carcinoma of the left breast, which was treated with radium needles. One of these, which had been inserted into the third intercostal space, worked through into the pleural cavity, and could not be recovered by the use of a pair of forceps. She was not a patient of mine, but I was asked to help to recover the needle. Under the *x* rays it was seen to move with the lung, under the inner end of the third rib, and could be touched with the forceps but not held. After some considerable time spent in these efforts I decided that the only way to extract the needle was to open the chest. This was done, the lung of course collapsing, and with it the needle, which was found to have fallen into the costo-phrenic sulcus, and was picked up from there by the fingers after inserting my hand into the pleural cavity. The

patient was not inconvenienced during the operation, but suffered from cyanosis and dyspnoea for a day or two afterwards. However, she made a perfect recovery and the lung was fully expanded by the end of a week.

The principles of the technique of the operation were the same in the three cases; minor differences consisted in the removal of different ribs according to the one to which the growth adhered.

In performing the operation as a means of access to the pleural cavity it was found in the war cases most convenient to reflect the fourth rib; this seemed to give the most direct approach to the pleural cavity as a whole. An incision is made in the axis of this rib, the pectoral muscles split, and the rib reflected subperiosteally. In older patients it seems wiser to remove the rib. The pleura is divided in the same direction as the skin incision and to such an extent that the hand may be passed into the chest. If a rib spreader be inserted and opened widely the whole of the pleural cavity can be easily inspected. The most difficult part of the operation is the closure of the pleural membrane. This tears rather easily, and owing to the rigid structures overlying it will not pull together as the peritoneum does. Fortunately it does not seem to matter very much if a close approximation is not effected. Some slight temporary surgical emphysema sometimes follows, but by no means always. If the rib has been reflected it is stitched back into place by passing one or more sutures through the cartilaginous end into the cartilaginous piece left at the sternum, for the division should be made when possible through the cartilage in the first place. The muscles are drawn together with sutures, and finally the skin wound closed; no drainage is necessary unless there has been much bleeding and some risk of infection. In these circumstances it was found in the war cases that *it was much better to drain from the back* after completely closing the wound in front.

The anaesthetic used was ether in every case, given by the ordinary method of inhalation; any contrivance used to prevent the lung from collapsing would be a disadvantage, and the ordinary method seems to be quite safe.

THE RHEUMATIC TYPE.

BY

N. GRAY HILL, *M.C.*, M.B., B.S., D.P.H.,

AND

MARY ALLAN, M.A.

THE belief that a certain type of individual is particularly susceptible to certain diseases was at one time widely held, and, although this view is not generally accepted at the present day, references to the rheumatic type of child are still far from uncommon. It is believed by many that fair children, those having red, sandy, or auburn hair, are especially prone to develop rheumatic fever. Shrubsall examined 133 rheumatic patients, and, taking the colour of the hair as a criterion, found that 75.19 per cent. of these cases came under the heading of fair and 24.81 per cent. dark. Llewellyn and others have supported this theory, but have not given such exact figures. Shrubsall compared his findings with those of Beddoe, who examined 6,000 Londoners, of whom 58.4 per cent. were fair and 41.6 per cent. dark, and with his own records of patients suffering from non-rheumatic diseases, and his conclusions were that "the blonde traits are associated with acute rheumatism, heart disease, and tonsillitis."

For the purpose of comparison the characteristics of 562 rheumatic children, patients at either Queen Mary's Hospital, Carshalton, or the Downs Hospital, Sutton, have been recorded and are set out in Table I, together with Shrubsall's and Beddoe's findings. To make the investigation still more complete similar records have been kept relating to 536 other patients at Queen Mary's Hospital, all London children of the same age group as the rheumatics, but admitted on account of various orthopaedic and other non-rheumatic conditions.

TABLE I.—*Comparison of Rheumatic and Control Cases: Colour of the Hair (expressed as Percentages).*

	Fair Hair.			Dark Hair.		Total Fair.	Total Dark.
	Red.	Fair.	Light Brown	Dark Brown.	Black.		
Rheumatic cases:							
Shrubsall's 133 cases ...	21.05	21.05	33.09	23.31	1.5	75.19	24.81
Q.M.H. & D.H. 562 cases	6.4	15.9	27.9	48.6	0.18	51.2	48.78
Controls:							
Beddoe's 6,000	4.4	12.1	41.6	37.4	4.4	58.4	41.6
Q.M.H. 536	3.1	20.2	43.1	33.6	—	66.4	33.6

In this table it will be seen that there is no very significant difference between the findings for the two control groups and those for the rheumatic cases at Queen Mary's and the Downs Hospitals, but there is a very marked difference between these latter and those for Shrubsall's cases. This difference is brought out in a more striking manner in Table II.

In Table II the cases from Queen Mary's and the Downs Hospitals have been subdivided into the distribution adopted by Shrubsall, and it shows that while out of his 133 cases 47 had either red or fair hair and blue or light-coloured eyes, among our 562 cases there are only 60 in this category.

The theory has also been advanced that a large proportion of rheumatic children are non-pigmenters, and that unusual dryness of the skin is commonly met with among them. It is difficult to record in any simple table the various types of skin or degrees of pigmentation obtained, but the rheumatic patients at Carshalton are exposed to natural sunlight during the summer, and many of them have artificial heliotherapy during the darker months, and they seem to respond to it very much as do the other patients. All degrees of pigmentation are obtained and non-pigmenters are met with, but there seems to be no constant deviation from the ordinary response to light among the rheumatics. In a certain number of cases the skin has been found to be dry, but this condition is not more commonly met with among the rheumatic than among the non-rheumatic patients.

Conclusion.

A general survey of the patients or a special investigation of any particular characteristics leads to the conclusion that there is no type that can fairly be described as the rheumatic type of child.

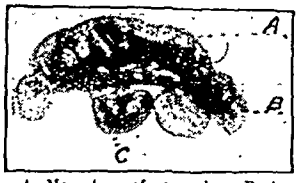
STRANGULATED POLYPUS OF THE VERMIFORM APPENDIX.

FREQUENT as are the causes which lead us to explore the region of the right iliac fossa, yet one more cause which I recently chanced to meet may prove of some interest. The features of the case are these.

A married woman, well nourished, aged 51, was admitted to hospital as a case of acute abdomen. The history of the illness was short. For forty-eight hours she had felt ill. Several times she had vomited, and for some twelve hours prior to admission pain had been present in the right iliac fossa. The pain had steadily become worse, so that, when seen, she felt she wanted to lie perfectly still to minimize the risk of increasing it. The temperature was 98.4° F., and pulse 72. The bowels had acted regularly. Her face bore a pained expression, but the tongue was moist and clean.

On examining the abdomen it was found to move freely with respiration. No marked guarding or congestion of the abdominal wall was noted over the appendix area. Pressure over McBurney's point elicited acute local tenderness. The urine was examined; it contained nothing to lead one to suspect any lesion in the urinary tract. Examination per vaginam was negative.



A, Mesentery of appendix. B, Appendix. C, Strangulated polypus.

The unusual sequence of events in the history, the lack of any systemic disturbance, and the famine of findings to the palpating hand made immediate operation seem unnecessary.

The following morning the patient was again seen. She still felt sick, but had not vomited since the previous evening. An enema had produced a good result. Fresh features in the case, however, were now present: the pulse had risen to 92, with a normal temperature; the tongue, though still clean, was dry. In the right iliac fossa deep tenderness could still be elicited, and there was now a fullness in that region and dullness to percussion. *Operation was the immediate decision.*

The abdomen being opened by a Battle's incision, it was noticed that the omentum had descended around the caecum, and a considerable effusion of peritoneal fluid had taken place. The omentum was displaced, exposing caecum and appendix. At first sight the appendix appeared quite healthy, but on turning it up into the wound it was seen to have three fibro-fatty polypi attached to its free border. The largest of these, as seen in the photograph, had become twisted three times upon its pedicle, was of a dark blue colour, and was verging on gangrene.

Appendicectomy was performed and the abdomen closed. No symptoms have since been present.

Lerwick, Shetland. Surgeon Consultant, County of Zetland.

CONGENITAL DIAPHRAGMATIC HERNIA.

IN view of the rarity of this condition I think that the following clinical and pathological details of a case of right-sided congenital diaphragmatic hernia are worthy of being recorded.

A woman gave birth to her second child after a normal vertex delivery; labour was three weeks premature. The infant was cyanosed, and this condition persisted, although respiration established itself immediately. The cry was fairly strong at first, but became gradually weaker, and soon ceased. The infant died one hour later.

Post-mortem examination revealed a large deficiency in the diaphragm on the right side. The spleen and stomach were in their normal positions, but the duodenum passed up into the right pleural cavity; this contained also small intestine, caecum, appendix, and the first part of the colon, which passed down through the diaphragm to become continuous with a normally situated descending colon. The liver consisted of two portions: a larger one below the diaphragm, and a smaller portion, which included the gall-bladder, above it; the two were connected by fibrous tissue and by a band of liver tissue. The mediastinum was displaced to the left. The right lung was rudimentary, each lobe measuring no more than [illegible] of an inch in any direction. The left lung was [illegible] lobes were flattened between the chest [illegible] and the anterior border scarcely reached to the [illegible] line. Both lungs had expanded, and the lung tissue was pink and of normal consistency. The right lung was not cut, but portions of the left lung floated in water. No Tardieu's spots were found on the pleurae or pericardium. A further abnormality was the presence of both testicles in the abdomen.

Crowthorne, Berks. E. F. CHAPMAN, M.D.

Reviews.

RECENT WORK ON PHTHISIS.

METHODS of treatment change so quickly that such publications as the Recent Advances Series are invaluable to the general practitioner, too busy, as he usually is, for post-graduate study. The publishers are to be congratulated on their latest addition to this series, *Recent Advances in Pulmonary Tuberculosis*[1] by Dr. L. S. T. BURRELL.

The author has kept the real object of such a book clearly before him, and has not wasted his space on elementary considerations or textbook features. Indeed, it would seem that he has felt a lack of space (if he has not, his readers will), and that, excellent though his condensation is, there is much more that he could teach. It is to be hoped that when this valuable book appears in its second edition it will be twice the size. The introductory chapter on phthisiogenesis is in itself an excellent monograph. The author's views are largely based on Krause's teaching, and here we find the researcher's hypotheses adapted by the practising physician to his principles of treatment. The policies of prevention of infection as against immunization in prophylaxis are pithily discussed in the next chapter. In the chapter on diagnosis which follows there is an excellent section on the use of tuberculin, a practical method which is sadly neglected in this country in the diagnosis and study of tuberculosis in childhood. Radiology, the perfection of which is one of our most important recent advances, is very properly given a chapter to itself. Prognosis, so important in pulmonary tuberculosis, and so difficult to the practitioner whose experience is limited, is dealt with next, and it is here that the reader will undoubtedly ask for more.

The rest of the book (rather more than half) describes modern methods of treatment. A work of this size cannot, and is not intended to, teach in detail how these various treatments are carried out, but rather to suggest what treatments are possible, and the types of case for which each is suitable. In this part special features have been made of sanocrysin and artificial pneumothorax treatment. The book contains some very good *x*-ray illustrations, and short bibliographies are appended to each chapter. The pleasant style and good print make it so easily read that there is no excuse for its absence from the bookshelves of even the busiest general practitioner.

OPHTHALMOLOGY.

THE issue of a second edition of Mr. DUKE-ELDER's book on *Recent Advances in Ophthalmology*[2] within eighteen months of the first appearance of the work is a certain indication that it has met a need, and it justifies the commendatory review that we gave the first edition. In the new edition there has been included some 370 new references, and to keep the book within its original limits earlier references have been omitted. The chief new inclusions deal with Adrian's work on optic nerve currents, Mann's work on the embryology of the vitreous body, and radiological investigations of the lacrymal passages which has been greatly advanced by the use of lipiodol. There is a good account of the work published in 1928 by Ploman, Engel, and Knutson on the physiology of the process of the conduction of tears, and matter that has long been in dispute and now may be taken as settled. Mr. Duke-Elder has set himself a high standard, and the second edition fully maintains it.

The book on *Squint*,[3] by Mr. CLAUD WORTH, the first edition of which was published in 1903, has now reached its sixth edition. The book has therefore secured a place for itself

[2] *Recent Advances in Ophthalmology.* By W. Stewart Duke-Elder, M.D., F.R.C.S., etc. Second edition. London: J. and A. Churchill. 1929. (5½ × 8½, pp. xviii + 405; 110 figures, 4 plates. 12s. 6d.)
[3] *Squint: Its Causes, Pathology, and Treatment.* By Claud Worth, F.R.C.S. Sixth edition. London: Baillière, Tindall and Cox. 1929. (Demy 8vo, pp. ix + 246; 42 figures. 10s. 6d. net.)

and become recognized as having a definite value in the consideration of that most interesting and perplexing disorder of the eyes which gives the name to the book. There have been no fundamental changes in successive editions, though the matter has been added to from time to time, and improvements in the technique of treatment have been duly noted. The main service of this book has lain in the fact that it was an intensely personal production; it represented the practice and achievements of one man who had devoted almost the whole of his professional interest to the investigation and treatment of this one disorder, and with a success that has been enviable. We have no doubt that the lesson stressed by Worth, that the amblyopia of the squinting eye was a defect of negligence, has been so learned that it can never be forgotten.

A second edition of the German textbook on ophthalmology[1] written by Dr. A. BRÜCKNER and Dr. W. MEISNER has now appeared. It is larger, more complete, and more luxuriously published than the first, which was written soon after the war. The book is intended for the student and the general medical practitioner, but, judged by the standards of this country, it is a somewhat large and portentous volume to cater for these classes. Theoretical subjects are dealt with in considerable detail, and on the whole are more adequately treated than purely clinical matters. It may seem strange, for example, that extremely important clinical conditions, such as retinitis in association with arterio-sclerosis and diabetes, are very cursorily treated. The slit-lamp, also, is disposed of in one paragraph only. The pathological aspects of the various clinical conditions receive an adequate amount of attention. The illustrations are good, although it is disappointing to find that the common practice is still retained to some extent of copying from the old classical drawings and transcribing not only their undoubted excellencies, but also their mistakes: an example of this is seen in the insertion of the levator palpebrae superioris in Fig. 12. On the whole, however, the book is sound and its teaching good; it is up to date and well published, and should take a prominent place in German ophthalmological literature.

SERUM DIAGNOSIS BY COMPLEMENT-FIXATION.

IN *Serum Diagnosis by Complement-Fixation*[2] Professor J. A. KOLMER takes a broad view of his subject. Though by far the greater part of the book is devoted to syphilis, it includes also short sections on complement-fixation as applied to a large variety of other subjects, notably tuberculosis, gonorrhoea, echinococcus disease, and numerous other bacterial, protozoal, and metazoal diseases, as well as for the detection of meat and milk adulteration and the identification of blood and seminal stains.

The author's plan—after dealing with the principles of the reaction—has been to take each reagent separately and explain its nature and action in detail in the light of his own experiments. Considerable attention is paid to antibody, antigen, and complement; on the other hand, haemolysin is somewhat briefly considered, which is unfortunate, as its importance is only too commonly underestimated. Anti-complementary action is very fully considered; possibly its importance is greater with the author's long fixation technique than with the short fixation employed by most workers. The author's own test is described with great minuteness of detail, and stress is very properly laid on the necessity of strict adherence to the technique described in order to obtain the best possible results. The test is a somewhat laborious one, and the technique none too simple, but it appears to possess the two principal desiderata—a high degree of sensitiveness with almost absolute specificity. The section dealing with specificity is particularly good. The author definitely disposes of the bogy of "false positives," yaws being the only disease besides syphilis which gives a positive reaction with his test. Such diseases as scarlet fever, typhoid, tuberculosis, malaria, and the long list of others to be found in almost every textbook on the subject are definitely ruled out; nor is the author able to confirm the statement that alcohol may temporarily convert a positive reaction to negative. The sections devoted to complement-fixation in the diagnosis of other diseases and for other purposes are rather curtailed, and consist of short references to the literature, together with some account of the author's own experience. It might have been better to have devoted a separate volume to these, seeing that the book runs to nearly six hundred pages, whilst only four of these deal with the subject of complement-fixation in gonorrhoea.

Professor Kolmer's experience of complement-fixation must be immense, and in his latest book he has given a masterly and lucid survey of its principles and technique, no detail being too small for consideration. This work will be appreciated most by serologists, but if clinicians who undertake the diagnosis and treatment of syphilis would study its contents with care they would gain a clear idea of what the Wassermann reaction means, what is its value, and what are its limitations. The book is well produced and the printing and paper are excellent; italics are used to bring out points of special importance, and the illustrations are remarkably clear. The bibliography, given at the end of each chapter, is more than adequate, though British authors have been rather neglected. Both author and publishers are to be congratulated on the production of a really valuable addition to the already voluminous literature on the subject.

BASAL METABOLISM.

PROFESSOR MARCEL LABBÉ and Dr. H. STÉVENIN in their textbook on basal metabolism[6] give a good summary of modern knowledge of this subject in a volume of moderate size. The authors have the advantage of a first-hand acquaintance with their subject, and in many cases quote results from their own experiments. One particularly interesting feature of the book is that the authors discuss at some length the factors determining the basal metabolism of the normal subject, and give a reasoned account of the theories regarding the relations that have been shown to exist between basal metabolism and body weight, body surface, external temperature, and nutrition. The significance of these relations is still obscure, but unless they are taken into account it is difficult to estimate the meaning of the variations in basal metabolism observed in disease. The greater part of the book is devoted to basal metabolism in disease, and a particularly full account is given of the variations of basal metabolism in thyroid disorders. The variations of basal metabolism in other endocrine disorders and in numerous forms of disease are also discussed. The last chapter contains an account of the various forms of apparatus used in the determination of basal metabolism. The volume concludes with thirty-five pages of useful tables of constants.

VERTEBRATE ZOOLOGY.

DR. G. R. DE BEER'S *Vertebrate Zoology*[7] forms one of the series of textbooks of animal biology that is being edited by Professor JULIAN HUXLEY. The word "zoology" to most medical men probably recalls somewhat vague and confused memories of such things as the appendages of the crayfish and the skull bones of the frog. A perusal of this book will show them, however, that changes are taking place in this subject. The editor, in an introduction, points out that morphology is only one branch of zoology, and that indeed morphology cannot be understood unless studied in relation to genetics and physiology. He also points out how necessary it is to avoid stupefying the student by making him learn masses of detail. The textbook is composed along these lines of thought. A series of

type species of vertebrates are described in Part I. The next part deals with four embryological types, and the comparative zoology of each system of the body is described in Part III. This last is the longest part of the book. Part IV is headed "Evolutionary morphology," and in it are discussed the mode of evolution of the various classes of vertebrates. In the last chapter the author discusses such problems as the homology of organs in vertebrates, convergence of evolution, and the distinction between primitive and specialized types. The appearance of this textbook is of particular interest, as it is a sign of the change of outlook that is taking place among teachers of zoology.

NOTES ON BOOKS.

DR. EDWARD GLOVER is responsible for a monograph on *The Technique of Psycho-Analysis*,[8] which is unquestionably the most comprehensive and detailed account of the mode of therapy with which it is concerned that has hitherto been written. Its subject-matter is classified under the following headings: the analytic situation; the opening phase; defence-resistance; counter-transference and resistance; the transference-neurosis; terminal phases; "active" therapy; and analytical crisis and exceptional cases. Dr. Glover explains that the difficulties of analytic technique are twofold: those relating to the patient and those relating to the analyst himself—a difficulty that can only be obviated by analysis of the analyst. We should imagine that those who intend to apply analytic treatment would find this work an indispensable part of their equipment.

The seventh edition of the textbook on experimental bacteriology and infectious diseases[9] by Professors W. KOLLE and H. HETSCH of Frankfort, which has appeared more than six years after the last, consists of two volumes containing seventy-two lectures, of which the first twelve are introductory, while the remainder are devoted to the consideration of the various infectious diseases. The work has been carefully revised throughout. In order to find room for the fresh acquisitions to knowledge without unduly increasing the size of the volume, the lectures on the microscope and the doctrine of disinfection have been omitted, as well as the chapters on animal parasites, such as ankylostomiasis, trichinosis, filariasis, and bilharziasis. The new matter is represented by lectures on bacteriophagy, tularaemia, and scarlet fever. Encephalitis epidemica now receives special consideration in a lecture which also treats of related processes in man and animals, including the herpes virus. The work as a whole has been thoroughly revised and brought up to date, and many new illustrations have taken the place of those in the previous edition. The well-deserved popularity of this book, which appeals alike to pathologists, clinicians, and epidemiologists, is attested not only by its having reached the seventh edition, but also by its having been translated into French, Spanish, Italian, and Russian.

Sir JOHN O'CONOR was a brilliant and versatile Irishman who went to Buenos Aires early in his medical career, and for nearly forty years was connected with the British Hospital in that city. The posthumous publication of his *Reflections and Operations*[10] is prefaced with a foreword by Mr. Herbert J. Paterson, who calls sympathetic attention to Sir John O'Conor's enthusiasm for drainage in sepsis and for the complete immobilization of fractures. With the author's belief in the value of alcohol Mr. Paterson naturally does not agree, and he protests mildly against such statements as: "Universal total abstention would tend in a comparatively short cycle of time to depopulate the earth"; and "Teetotalism is a frequent cause of arterio-sclerosis." Many of the short essays which form this volume were contributed to various British medical journals. The style is vigorous, but homely; the matter occasionally stimulating, but generally not very important. As a record of the observations and opinions on surgical subjects of a man who had an enormous and varied experience in almost every branch of the art the book has its value.

A small handbook[11] by various French authors has been prepared describing the French spas of Evian, Mont-Dore, La Bourboule, Aix-les-Bains, Néris, Cauterets, Biarritz, Aix, Vichy, Royat, Bagnoles de l'Orne, Chatel-Guyon, and Vittel. In each case the special value of the local mineral water is indicated, and an account is given of the various clinical indications for its use. The practical details supplied as regards local amenities will be appreciated by general practitioners, who can obtain the handbook, which is supplied without charge, on application to the Manager, Federation of the Health Resorts of France, 1, Gordon Square, W.C.1.

The little work entitled *Alcohol and Human Life*,[12] by Dr. COURTENAY C. WEEKS, is, as its subtitle states, partly a revision of certain facts and figures in the last edition of *Alcohol and the Human Body*, by the late Sir Victor Horsley and the late Dr. Mary Sturge and others. The book deals with the use of alcohol in medical treatment, the effects of alcohol on the nervous system, the skin, the liver and kidney, blood and circulation and the duration of life; as well as the influence of alcohol on national life.

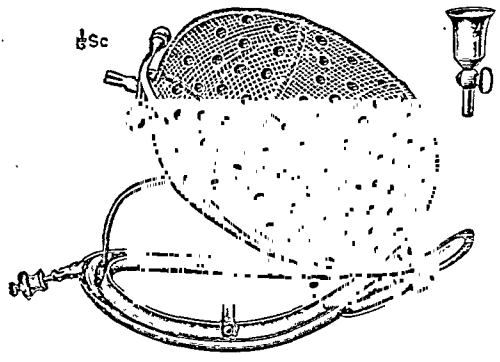
PREPARATIONS AND APPLIANCES.

AN ETHER INHALER.

DR. G. A. METCALFE (Bedford) writes: May I introduce an ether inhaler which I have found to be efficient in practice and economical in use? It has for its basis the principle of a vapour space, which is obtained by superimposing an outer wire gauze cage on a Schimmelbusch face-piece. The gauze is perforated at short intervals, and when in use is covered with one or two layers of lint held in position by a spring. The outer cage, when clipped down, holds the face-piece lint in position, and ether is introduced by a small funnel through the perforations in the gauze. A feed pipe is fixed near one end of the face-piece, through which oxygen or oxygen and ether vapour can be introduced under the mask. The cage is



so constructed that it can be completely removed, and the mask used as an ordinary Schimmelbusch by fixing a wire retaining ring in its place.

When in use anaesthesia can be maintained either by blowing a slow stream of oxygen through ether into the mask through the feed pipe, the proportions of ether and oxygen being ideally maintained by such an apparatus as Mennell's bottle and by-pass, or by gently dripping ether through the gauze by the funnel. In all cases it is advantageous to use oxygen while maintaining anaesthesia. By adding an extra layer of lint to the cage, or by covering with a layer of gamgee, the anaesthesia can be deepened at will.

The advantages given by the inhaler are: (1) ease and uniformity of anaesthesia; (2) clear view of the face during anaesthesia; (3) extraordinary economy in use. I would like to thank Dr. Z. Mennell, senior visiting anaesthetist, and Dr. G. Edwards, senior resident anaesthetist, of St. Thomas's Hospital, for testing the inhaler and for their very helpful suggestions. The mask is made by Messrs. Down Bros., Ltd., St. Thomas's Street, London, S.E.1.

HIGH-TENSION TRANSFORMER UNITS.

Newton and Wright, Ltd. (471–3, Hornsey Road, N.), forward us a booklet containing a brief description of their standard transformer units for radiology up to a tension rating of 150 kilovolts. Such transformer units, with some arrangement for rectifying the high-tension current, form the basis of practically all modern *x*-ray plants of any size. Broadly speaking, a high-tension rectifier can be either mechanical or thermionic (the latter depending upon the action of a hot cathode valve). The booklet contains particulars of both kinds of plants—namely, the well-known Snook machine with mechanical rectification, and the mono-valve and tetra-valve outfits with hot cathode rectifiers.

SCARLET FEVER, DIPHTHERIA, AND ENTERIC FEVER.

A CLINICAL-STATISTICAL STUDY.

THE correlation and interpretation of clinical statistics gathered from various sources is subject to such possibilities of error, owing in part to the variation in the nature of the populations from which the material is drawn, in part to inevitable differences in the standards of classification adopted by various observers, that special value attaches to the clinical-statistical study of scarlet fever, diphtheria, and enteric fever which has recently been made by Dr. E. W. Goodall, Professor M. Greenwood, and Mr. W. T. Russell from data derived from a single source.[1] The case records having been compiled throughout under the supervision of Dr. E. W. Goodall, who personally examined all but a few of the patients, Professor Greenwood and Mr. Russell were able to deal with data free from many of the discrepancies which could hardly be avoided in records collected on a less uniform basis. The scope of the inquiry includes all the patients suffering from the diseases in question admitted to the Eastern Fever Hospital of the Metropolitan Asylums Board during the period 1895 to 1914, and covers 21,280 cases of scarlet fever, 15,239 cases of diphtheria, and 2,434 cases of enteric fever, all corrected for errors of diagnosis. From this material information has been gathered on the age distribution of these diseases, their seasonal distribution (with the associated question of the influence of school closure upon their prevalence), their fatality, and variations in form and complications.

SCARLET FEVER AND DIPHTHERIA.

Seasonal Distribution.

In the opinion of the authors of the report, the most interesting point brought out by a study of the records is that while in the incidence both of scarlet fever and diphtheria the seasonal variation is large, the amplitude of the excursions decidedly increased in the more recent period of scarlet fever, the difference between the seasons of its maximal and minimal incidence being greater in 1905–14 than in 1895–1905. A similar change has not affected diphtheria. Speculating on this contrast the authors suggest that the incidence from day to day or from week to week of an infectious disease may depend on two sets of factors, one largely independent of social organization, the other amenable to control. The seasonal factors, in which may be included changes of temperature, and biological changes in the proportion of susceptibles so far as these are determined by seasonal variations of human fertility, are, as a whole, persistent, though some—for instance, insect prevalence—may be modified by human action. On the other hand, such factors as overcrowding, lack of sanitary supervision, and so forth, which operate more or less uniformly throughout the year, are subject to control; it would follow that the more important the second group of factors the greater its tendency to swamp the seasonal variations with a large steady quota of infections. An accentuation of the seasonal swing may, therefore, from a sanitary point of view, be regarded as a favourable sign.

The authors find that while the data for scarlet fever do not suggest that school closure produces any disturbance of seasonal rhythm, the sharply contrasting trends of the graphs for children of school age and for adults obtained from the diphtheria data do suggest that school contact is a more important environmental factor of diphtheria than of scarlet fever. They are careful, however, to add that they do not set up conclusions derived from their own relatively small collection of data in opposition to those obtained from the notification statistics of the whole County of London.

The graver, septic, form of scarlet fever appears to be less sensitive than the milder form to the uncontrollable seasonal variations. In the diphtheria series the forms studied varied in proportional frequency with season, but the maximum and minimum did not occur at the same time of the year. The incidence of the croup-laryngeal form tends to a maximum in the spring; the maximum of seasonal fatality, however, occurs in the winter. With respect to complications, their tendency in scarlet fever is to be relatively more frequent in the first six months of the year—that is, in the period when the rate of mortality is highest. The most serious complication of diphtheria—paralysis—however, tends to be more prevalent in the second half of the year, while its mortality appears to be highest in the first half, the period of greatest prevalence of otitis and of the croup and laryngeal forms of the disease.

Age Distribution and Secular Trend.

The data show that in scarlet fever the septic form diminishes in relative frequency from the third year of life. In diphtheria the rhinorrhoeal form decreases with age in a geometrical progression, while the croup and laryngeal form descends from a maximum in the second year of life. The data are valuable in confirming the conclusion that two of the most serious complications of scarlet fever—otitis and nephritis—are becoming less frequent, as also is otitis as a complication of diphtheria. Though paralysis in diphtheria has not decreased regularly, each quinquennium subsequent to 1900–4 shows a fall.

ENTERIC FEVER.

Age and Seasonal Incidence.

Study of the data shows that the modal or most frequent age at which the enteric patients were admitted to hospital was 13.61 years, the mode having tended to shift to later ages in the last two quinquenniums; the proportion of cases with complications—namely, 48.5 per cent. of the total—did not vary appreciably in each of the four quinquenniums. The age incidence of the complicated cases was 2.637 years greater than that of the uncomplicated cases—namely, 21.713 ± 0.231 years, as compared with 19.076 ± 0.209 years. This difference, in the view of the authors, is statistically significant, and is greater in degree than can be accounted for by mere chance. They calculate that the odds are more than 70,000 to 1 against the occurrence of two such divergent distributions if they were random samples from the same population.

The seasonal incidence of the admissions corresponded with that observed for the notifications throughout England and Wales; the maximum frequency was in September, but complicated cases occurred relatively more frequently in the first half of the year.

Complications and Fatalities.

Females showed a greater tendency than males to contract complications, 51.7 per cent. having been thus affected, as compared with 45.8 per cent. of males. The relative position, however, is reversed in the case fatality, which was 16.42 per cent. among males and only 12.82 per cent. among females. The proportional frequencies of the chief complications in enteric, as shown in the data under consideration, are 11.18 per cent. for relapse, 6.94 per cent. for haemorrhage, and 4.40 per cent. for perforation; the case rates for these complications increase with age. The lesser complications, such as otitis and secondary rash, appear to have a higher incidence at the earlier periods of life, while the rates for pneumonia and abscess show very little variation with age. During the whole period the fatality among enteric patients was 14.79 per 100 admissions. During 1895–99 the fatality ratio was 18 per cent.; it dropped to 12.7 per cent., its minimal value, during the quinquennium 1905–9, and in the final period increased to 15.6 per cent.

CONCLUSION.

The authors are careful to point out that as their data refer to patients not drawn wholly from one district, and to a period during which public resort to institutional treatment has undergone change, they cannot throw light upon the real incidence of the diseases under survey, and that even the statistics of fatality have to be interpreted with great caution. The analyses of the forms and complications of the disease, however, are of unusual value, and the Medical Research Council believes that these will be of special interest to clinical epidemiologists.

SATURDAY, SEPTEMBER 14TH, 1929.

SILICOSIS IN RELATION TO INDUSTRY.

A GOOD example of the pathological change brought about by dust inhalation was contributed by Dr. P. Heffernan, tuberculosis officer in Derbyshire, in a paper which he read before the Section of Occupational Diseases at the Annual Meeting of the British Medical Association at Manchester; the paper is published in this issue at page 489. According to King's table, which is cited by Dr. Heffernan, a normal lung contains 1.40 mg. of silica per gram of the organ, and a silicotic one 123.55 mg.; silica is thus a normal constituent of the human body, and in no sense a poisonous substance. In order to operate actively it must enter into the intimate structure of the cell, and Heffernan regards the resulting fibrosis as being of a physico-chemical nature, due to the local action of hydrated silica upon the pulmonary tissue. There is some evidence, moreover, that certain substances —alkalis for instance—favour the formation of silica hydrosol from silica, accelerating the fibrotic development; others—for example, coal dust and clays—retard or inhibit this process. In this way an explanation is afforded of the very few cases observed of so-called "acute" silicosis (developing within two or three years of constant exposure, and then following a rapid course) from inhalation of a mixture of silica dust and strongly alkaline dried soap. In a similar way the absence of disabling silicosis among coal miners and fireclay workers can be explained. Gye and Kettle's experiments have led to the belief that the inhaled silica particles undergo slow hydration into silica sol. One might go further and say, the more soluble the form of silica becomes (hydrated, amorphous, crystalline) the more readily will it set up fibrosis.

All observers in South Africa and in this country are now agreed, as Dr. E. L. Middleton states in his paper, published to-day at page 485, that the phagocytes, when overloaded with the dust, lose their motile power, collect in the lymphatic channels, and lead to a reaction, with formation of fibroblasts, in the surrounding tissues. Here in this colloidal reactivity of the cell we are in the presence, as Heffernan suggests, of something analogous to the mysterious change in the vital behaviour of a cell when it takes on malignant growth.

These theoretical considerations, though interesting, do not give much assistance in solving the practical problem how to control the malady. The more widely radiological examinations are made of the lungs of workmen, in no matter what dusty occupation—coal miners, millers, cement workers—the more generally is some fibrosis found to be present in all. Only exceptionally, however, as in the case of the absorption of asbestos dust, is the process likely to develop so as to interfere with the normal working capacity and with life. Some standard, therefore, of what constitutes an injurious amount of silica dust is demanded, or legislation will become punitive on some quite harmless industries. Thus Middleton says: "Where the amount of dust is small the action of the phagocytes is likely to be effective, but where it is great . . ." What dosage is indicated by "small" and "great" in this connexion? If the meaning of "small" were known, would it be correct to go on to say, as he does, "each successive dose of silica produces a summation of effects"? Then, again, would it be fair to say, "a comparatively brief period of exposure may be the only determining factor"? What, in minutes, hours, or days per week, per month, or year, is intended by "a comparatively brief period"? "Intermittency of the process" is another expression used in summing up the reasons for and against a standardization of air purity by a gravimetric process or enumeration of the particles; the arguments against such a standardization are, by Middleton, considered strong, but they are by no means convincing to us. A standard has been accepted in respect of the amount of lead in milligrams per 10 cubic metres of air; Dr. Ronald Lane showed in another paper read that adherence to this makes the occurrence of poisoning highly improbable. Mavrogordato has placed on record figures of silica dust at different stages of the improvements in the workings of the Rand mines, and such a control is in constant operation in them to-day.

We emphasize these points because apparently the Government has taken the unusual course of legislating first and postponing inquiry to a later date, as in the "Various Industries (Silicosis) Scheme, 1929." The insurance companies also have a considerable interest in the matter of compensation for the silicosis risk. Where exposure—as in the refractories industries, the grinding industries, sandstone industry, and pottery industry—is day in and day out, they rightly demand a premium far higher than for any other disease scheduled under the Workmen's Compensation Act—5 per cent. on the wages bill. Now every industrial employer, such as the paint and varnish manufacturer, who has a sack of crushed silica in his store room, from which he extracts once a week enough to make a paste with spirit and add to his other ingredients in order to give them the necessary "bite," becomes involved, and may have to abandon the use of the material or pay 5 per cent. on his wages bill for an absolutely negligible risk. For meting out justice standardization seems urgently called for.

The problem of silicosis in South Africa is now different from ours; the stages we have to traverse have there been passed. Dr. Irvine, in the report on the work of the Miners' Phthisis Medical Bureau for the year ended July 31st, 1928, describes the position *qua* simple silicosis as enormously improved since 1916, the date of the inauguration of the Medical Bureau. This improvement has been achieved through initial and periodic medical examinations, the application of exhaust ventilation, and watering. Water, however, while allaying coarse dust, is not equally efficacious in coping with the invisible dangerous variety. This very fine dust, the particles being of the order of under 2 μ, should, he says, be treated as a gas and be dealt with by ventilation. The excessive use of water is disadvantageous, moreover, facilitating the entry of the tubercle bacillus, and this constitutes the main problem in that country to-day.

THE NATURE OF RACE PREJUDICE.

Is race prejudice an acquired or an inborn element in man's mentality? Until now the majority of anthropologists have held that it is inborn and is necessary for the maintenance of racial purity. Another school of anthropologists is making its voice heard; Dr. Franz Boas, Professor of Anthropology in Columbia University, has recently expounded the views of this later school.[1] Seeing that for the greater part of his life he has professed anthropology in the city of New York, Dr. Boas ought to know something of the manifestations which are evoked when diverse races meet and mingle. He is of opinion that the clash which attends the contact of races is the result of acquired prejudices which are grafted on children by parents, teachers, and politicians, and that the sooner such behavioural manifestations as patriotism, national spirit, and race consciousness—especially that superior form entertained by Nordic anthropologists—are swept away, the better will it be for the peace of the world and the future welfare of mankind. These are opinions which have been held and promulgated these ten years past by that brilliant English man of letters Mr. H. G. Wells.

Anthropology has ceased to be a speculative study in the United States of America and has passed into realms of practical politics. Since the war enactments have particularly favoured immigrants from the north and west of Europe; the peoples from the south and east of that continent are handicapped; all the other racial products of the world—save white men—are barred. American legislators have thus adopted the tenets of the " purity school " of anthropologists and seek to make the population of the United States as Nordic as may now be possible. Dr. Boas, who was born and educated in South Germany, and has the advantage of viewing the peoples of the world with a denationalized detachment, looks upon the discrimination made by the immigration laws of the United States as based on an anthropological error. He does not believe in the inequality of human races. What he does believe is that in every race of mankind there is an extreme range of mental and bodily qualities; that the top third of one race —be it white, yellow, or black—is much the same as the top third of another race; and that what the United States should have done was to skim the top third of mankind, irrespective of colour, and in this way improve its native stock.

Such teaching concerns us all—particularly medical men, who are by calling students of human nature. Could men and women constituted as they now are become willing participators in racial intermarriage? If so, would it be to the ultimate advantage of mankind to endeavour to break down racial and national frontiers and by free intermingling cover the earth with a uniform carpet of humanity? Dr. Boas is of opinion that the advantages would be very great. The racial problems of the United States, of South Africa, of India, of every Government and continent of the world would disappear. There would be no need to maintain armies and fleets; nothing would remain to defend or to conquer; a universal police would alone suffice. It is quite true that with the progress of civilization national units have become ever larger; it seems possible that the ultimate unit might become world-wide. And yet there is something in man's nature which rebels against big national units. After the war there was a sudden relapse in favour of small nationalities. Nor are we certain that racial uniformitism would end strife; we cannot hope for a greater racial uniformity than now prevails in those parts of China where warfare has been endemic for years. Nor do the instances of hybridization which Dr. Boas cites from Brazil, Mexico, and Haiti strike us as particularly successful experiments. Racial uniformitism, even if it could be maintained, has only advantages of the most doubtful kind to offer the world.

Is, then, race antagonism so deeply ingrained in human nature that it cannot be uprooted? Dr. Boas admits that race consciousness is so charged with feeling and passion among the white men and women of the United States that a rational and cool consideration of his proposals is not possible at the present time. He believes, however, that he could eradicate race prejudice from any child if he caught the child young enough. He emphasizes the fact that the negro appears to be destitute of any inborn antagonism to white men and women. He rightly points out that there is no sex antagonism between men and women of the most diverse races—which he can prove by citing many instances. He is of opinion that if race antagonism was organically ingrained it would become manifest first as a sexual aversion. Herein students of human psychology will recognize an error; sex reactions are manifestations of individuals, whereas race reaction comes into operation only when men and women act as members of a crowd, tribe, or community. The early English settlers in America set up communities: they had their wives and children with them. Race antagonism became manifest in the community, and purity of blood was upheld. The Spanish conquerors left their wives and children at home; there was no community in which race feeling could become manifest. The result was hybridization. It is only when we probe into the evolution of human races that we perceive the part played by the feelings evoked by racial contact. We then see that racial differentiation, with the evolution of the highest forms of humanity, could never have come about unless race consciousness had been, and remains, an organic factor in man's mental outfit.

CONTROLLING RHEUMATISM IN KENSINGTON.

UNDER the Kensington (Acute Rheumatism) Regulations, 1927, acute rheumatism was made a notifiable disease in that borough for three years from October 1st, 1927. The regulations define acute rheumatism as denoting the following conditions occurring separately or together in a child under the age of 16 years: rheumatic pains and arthritis, if accompanied by a rise of temperature, rheumatic chorea, and rheumatic carditis. The results of the first year's working of this scheme of notification, with the investigation and supervision that resulted, are given in a special report[1] by Dr. James Fenton, the medical officer of health, and the consulting physician, Dr. R. C. Lightwood. During the period under review 159 cases of acute rheumatism were notified, and careful checking of these cases seems to suggest that even under the clear terms of the definition quoted above an error of 10 per cent. may easily arise, and this must be borne in mind in all statistics concerned with juvenile rheumatism. Cases notified were investigated as regards environmental conditions by health visitors, and certain interesting results appear from this investigation. The percentage of rheumatic cases coming from damp houses was just under 40, a figure which is lower than that for the British Medical Association's series of cases reported by Dr.

[1] First Annual Report on the Rheumatic Scheme of the Royal Borough of Kensington.

Reginald Miller, and rather more than the figures obtained in the Medical Research Council's report. The correspondence between the area from which the rheumatism notifications came and the "flood" areas of certain parts of the borough was not, however, by any means a close one, and it is suggested that dampness of the site is not the important factor unless the housing is in some way defective, or, alternatively, that the general social and hygienic conditions are just as important as the dampness itself or even of greater importance. For another possible explanation of the distribution of cases within the borough the rat-infested areas were investigated, and here again a certain slight degree of correspondence was found. But a point of further interest, which illustrates the difficulty of drawing hard-and-fast conclusions without complete knowledge of the problem, is that the rat-infested areas correspond more or less to the railway lines within the borough, and, further, the railway lines frequently follow the beds of old streams, bringing the position round to dampness again as a possible source of danger. It is concluded in a summary of the report that notification in itself must not be regarded as a therapeutic measure, but that the rheumatism supervisory centre is to be looked upon as the keystone in the structure of any local rheumatism scheme. Drs. R. C. Lightwood and M. L. Davies, in a paper which we publish this week at page 495, give some account of the clinical aspects of the work at the Kensington Rheumatism Supervisory Centre supplementing the report mentioned above. They emphasize that the main aim of such a centre is "to make use of all the measures available for preventing relapses in rheumatic children, and, secondly, to supervise the after-care of children already the victims of rheumatic heart disease." The difficulty of diagnosing mild grades of rheumatism was experienced by these workers as by others, and, especially with regard to "growing pains," they appear to have steered a careful middle course, including "patients in whom limb pains occurred persistently for weeks and months if no explanation other than rheumatism was forthcoming." The statistical study they present of 200 cases passing through the supervisory centre brings out many points of extreme interest. One side-light which possibly has some bearing on the relationship between tonsillectomy and rheumatism is revealed in the remarkable analysis of the 85 children out of the 200 in whom an operation for tonsillectomy had been performed. Of these 53 per cent. had suffered incomplete removal of the tonsils, and it would be an interesting study to try and ascertain whether this failure was due to any particular type of operation. This, however, is, as we have said, merely a side-light. The main facts with regard to rheumatism within the borough of Kensington have been well brought out and represent an important contribution to the study of the rheumatic problem. The experiment of notification has the sanction of the Ministry of Health, and the results of the three years experimental period will be studied with great interest. The first year's work indicates quite clearly the usefulness of the scheme when it is intelligently worked.

FROM PYORRHOEA TO MALARIA.

IN 1924 a proprietary preparation of the name of "aseplene" was advertised to the public of this country as "the only known cure for pyorrhoea of the gums." Its claims were described as based upon the experience of four and a half years' use in treatment at the Aseplene Clinic in Bedford Street, Strand, and grateful patients were said to "hail from all quarters of the world—India, South Africa, Rhodesia, etc." Either the name of this preparation has been applied to another proprietary remedy or, in process of time or of transit overseas, it would seem to have revealed new qualities calculated to recommend it for use in the tropics. Aseplene now appears in Malaya as a remedy for malaria. We learn from the supplement to the *Federated Malay States Government Gazette* for June 21st last that at a meeting of the Malaria Advisory Board the acting director of the Institute for Medical Research, F.M.S., reported that a supply of this drug obtained from the agents was used according to the printed directions for the treatment of ten cases of malaria. "The drug had no effect on temperature, the parasites increased in number, enlarged spleens became larger, and haemoglobin decreased. Rigors occurred after five days' treatment. He considered aseplene useless as a preventive or cure for malaria." The Board recorded its opinion that, having regard to the experiments made, aseplene was unsuitable for the treatment of malaria. The Government of the Federated Malay States is being approached with a view to finding means of preventing the advertisement and sale of such drugs in Malaya.

PROTECTION OF HOSPITALS FROM FIRE.

THE modern hospital architect, in planning his buildings, takes careful account of the structural devices by which the spread of fire may be limited, and makes increasing use of fire-resisting materials. His predecessor, however, according to Dr. Gilbert Burnet, chief surgeon to the National Fire Brigades Association,[1] has in many instances bequeathed dangerous hazards to patients, staffs, and firemen. The design of a hospital, he holds, should be determined as much by the fire brigade chief as by the architect; indeed, in his view, the local fire chief is the only person qualified by skill and training to undertake the responsibility of preventing and extinguishing outbreaks of fire in hospitals. He deprecates the practice of placing the dispensary in the basement, maintaining that all spirits in bulk and all compressed gases in cylinders should be treated with the same respect and care as petrol, and kept in a well-ventilated cool room, away from the main building. Special precautions are needed in storing new scientific products in premises some of which were designed many years ago. In this connexion the increasing use of ethylene in modern anaesthesia has introduced a new fire hazard into the hospital; the vapour mixed with oxygen from any source is liable to explode the moment it is brought into contact with a hot cautery or a static spark. Similar dangers accrue from other mixtures, and it follows, therefore, that only cylinders containing the same kind of gas should be stored in the one compartment; all cylinders should be prominently labelled, and, as a further guide to their contents, painted in distinctive colours. The only cylinders to be allowed in the electro-therapeutic rooms are those containing nitrous oxide and carbon dioxide: these rooms should never be used for operations under ether, ethyl chloride, or ethylene anaesthesia, and their installation should be regularly inspected by an expert engineer. The special dangers that may arise from an imperfect system of storing x-ray films were only too painfully brought home to us all by the recent disaster at the Clinic Hospital, Cleveland, Ohio. In Dr. Burnet's view, the X-Ray and Radium Protection Committee—whose preliminary recommendations were the subject of comment in our issue of June 15th (p. 1089)—should, before further developing its proposals, establish contact with, and obtain advice from, the Fire Protection Committee. The risk of fire lies not so much in the few odd films left in the film-viewing room as in the storage of films in bulk, and it is therefore imperative that all hospitals should keep their used and unused films in a separate building, and draw from them only their immediate requirements. In operating

[1] The Fire Peril in Hospitals. *Fire*, July, 1929, p. 43.

theatres, whose atmosphere is liable to be charged with explosive anaesthetic vapours, probably the greatest source of danger is the static electrical spark generated from the highly polished fittings and surfaces. At present the best safeguard is to maintain in the theatre an atmospheric humidity of 60, but Dr. Burnet suggests that more desirable would be some system of "earthing" the theatre appliances by which the danger might be overcome even in a dry atmosphere. It is not generally realized that a faulty switch in the lighting circuit may be as great a hazard in the operating theatre as a naked flame. The fire brigade chief, according to Dr. Burnet, would not only make sure that all switches were spark-proof; he would advocate the enclosure of all lamp sockets in spark-proof shades, and protect the hospital against risks from electric radiators, electric bells, and telephone indicators.

HEALTH OF THE NAVY.

THE Admiralty is again to be congratulated on its continued effort to publish its annual statistical reports on the health of the navy with less delay than has been the case in recent years. The present volume[1] appears considerably less than a year after the issue of its predecessor, and it is to be hoped that the improvement in this respect will be maintained so that the interest of these records may not be dulled by the lapse of time. The incidence of disease in 1927 was 479.05 per 1,000, a decrease in comparison with the past five years' average, but an increase compared with 1926; this rise was chiefly due to a preponderance of influenza and diseases of the respiratory system. The average number of men sick daily was 1,916.09, a ratio of 20.55 per 1,000. The most frequent causes of sickness were injuries (7,350 cases), catarrh (6,393 cases), acute gonorrhoea (3,978), tonsillitis (2,908), and influenza (2,562). The number of persons finally invalided was 1,267, a ratio of 13.8 per 1,000; in 37 cases this was due to refusal of operative treatment. The chief causes of invaliding were errors of refraction (234 cases), diseases of the ear (199), and pulmonary tuberculosis (159). Among the more interesting cases recorded are blackwater fever, Henoch's purpura, Banti's disease, osteomalacia, and Yangtze fever (fatal). The number of deaths was 201, a ratio of 2.15 per 1,000. The chief causes of death were drowning (27), injuries (25), and pulmonary tuberculosis (20). There were seven cases of suicide. Over 12,000 vaccinations and revaccinations were performed during the year, and only one case of small-pox (in China) is recorded. The typhoid and paratyphoid fevers accounted for 18 cases with 2 deaths; pneumococcal infection of the lungs for 211 cases with 13 deaths; and pulmonary tuberculosis for 151 cases with 20 deaths. The last of these diseases showed a decrease in incidence, the African station having the highest case ratio and the East Indies station the lowest. As usual, the ships' cooks, marines, sick berth staff, and supply staff—those chiefly working between decks—provide the highest ratio, and from the smaller ships, such as submarine depot ships, submarines, and destroyers, came the largest number of cases per 1,000 of complement. Strangely enough, training establishments take second place in this list. Venereal diseases appreciably decreased. In addition to the 3,978 cases of gonorrhoea there were 436 fresh cases of syphilis and 927 of chancroid. Calomel cream and mercuric iodide soap are provided in the form of anti-venereal outfits. Dental treatment has been further extended, particularly in regard to appliance work, due to the larger number of dental officers. The returns show that 95 per cent. of newly entered personnel were in need of dental attention, and the number of those requiring extensive treatment has risen from 19 per cent. to 26 per cent. During the year all boys at the boys' training establishments and all band boys and bugler boys at the Royal Marine School of Music were re-examined and rendered dentally fit. A considerable amount of research work has been carried out at the Royal Naval Medical School, Greenwich. Among the subjects dealt with were the purification and regeneration of air in submarines, the purification of swimming-bath water, an improved method of analysing oxygen for therapeutic purposes, and the prevention of mould formation in tobacco. All members of the Royal Marine Battalion (982 officers and men) serving in China were given Professor Besredka's bilivaccin tablets—one tablet before breakfast on three successive mornings—as a prophylactic measure against bacillary dysentery. During nearly ten months' service in China only 7 cases occurred—4 bacillary, 2 amoebic, and 1 not specified. It is a matter for conjecture whether these very satisfactory figures were due to the bilivaccin or to general sanitary precautions. Eight cases of beri-beri, with 3 invalidings and 2 deaths, occurred in one sloop on service in the Persian Gulf. Two points of interest are recorded in this connexion: the sick berth rating who attended the patients contracted the disease, and only teetotallers were affected. It is presumed that the local beer contained the necessary vitamins.

HORNER'S SYNDROME OF PARALYSIS OF THE CERVICAL SYMPATHETIC.

THE names of two Horners are connected with the eye: William Edmonds Horner (1793–1853) of Philadelphia discovered the tensor tarsi muscle of the lacrymal apparatus, and Johann Friedrich Horner (1831–1886), a Swiss ophthalmologist, described in 1869 the symptom-complex variously known as the Claude Bernard-Horner syndrome (in France), Budge's phenomenon (among physiologists), and more correctly Horner's syndrome. Its clinical picture consists in endophthalmos, or a sunken and soft state of the eyeball; narrowing of the palpebral fissure; drooping of the upper eyelid and slight elevation of the lower; contraction of the pupil; and certain anomalies in the vasomotor and sudorific activities of the neck and face. It is seen in traumatic lesions of the cervical spine, tumours of the spinal cord, and many other conditions. Dr. J. F. Fulton, formerly working under Professor Harvey Cushing at the Peter Brent Brigham Hospital, Boston, and now of Magdalen College, Oxford, in a critical paper entitled "Horner and the syndrome of paralysis of the cervical sympathetic,"[1] has drawn an interesting picture of Horner, has translated his brief paper on "A form of ptosis," and given a summary of the history of physiological investigations on the relation of the cervical sympathetic chain to the eye. This last is an appropriate and useful commentary, since Horner omitted all reference to the data then established by experimental physiology, such as those in 1727 of the French surgeon François-Pourfour du Petit (1664–1741), William Cruikshank (1795), Dupuy d'Alfort (1816), John Reid (1839), Biffi (1834), Ruete (1847), and J. L. Budge (1851) of Grieswald, A. Waller (1851), and Claude Bernard in 1852. Considering the knowledge of the sympathetic control of the eye proved by experimental physiology, it is surprising that clinical correlation was not forthcoming until Horner's paper in 1869. The nearest approach to so doing was made by E. S. Hare (1812–1838), house-surgeon at the Staffordshire General Hospital, in a paper published in the month that he died of typhus fever, and recording a case of hard tumour involving all the vessels and nerves on the left side of the neck. Considerably after Horner's modest account appeared, the late Sir Jonathan Hutchinson described cases of the kind due to gross injuries of the brachial plexus.

THE EFFECT OF GAMMA IRRADIATION ON CELL DIVISION.

CONTINUING their well-known work on cell division in tissue cultures *in vitro*, Drs. R. G. Canti and F. G. Spear[1] have conducted experiments with a view to determining the rates of falling off and the subsequent return of mitosis in such cultures when exposed to the gamma rays of radium. In each series of determinations the selected intensity and duration of exposure was kept constant; the tissue used was obtained from the choroid and sclerotic of the chick embryo. Four series of determinations were made with different durations of exposures for each series—namely, 1½ minutes, 2½ minutes, 9 minutes, and half an hour. The subsequent determinations in each series were made at various intervals of time up to nine hours after irradiation had ceased. It was found that irradiation for 1½ minutes caused no significant reduction in the number of cells in mitosis during the subsequent three hours. When, however, the exposure was continued for 2½ minutes the number of cells in mitosis rapidly diminished until a minimum of 40 per cent. was reached in 80 minutes. After this time the number increased; the normal was regained in about two and three-quarter hours, but the increase continued until the end of the fourth hour, when the number of cells in mitosis was the maximum—namely, 160 per cent. of the normal. The number then progressively diminished, the normal being reached during the sixth hour, after which it remained constant. Irradiation for 9 minutes produced a greater initial fall—namely, to 27 per cent. of the normal in approximately eighty minutes. The number then rose to the normal as before, but reached a maximum of only 128 per cent., after which it again fell to the normal. After irradiation for half an hour it was found that mitosis had almost ceased after the next two hours, and that, although the number of cells in mitosis subsequently rose, it never attained more than 70 per cent. of the normal. The drop in the number of cells in mitosis was shown to be due to the fact that, while cells already in mitosis at the time of irradiation continue to divide in an apparently normal fashion, other cells do not enter into mitosis. The authors suggest that the return of mitosis may be due to the renewed activity of those cells which were about to go into mitosis, but were inhibited. They add that the following factors may be concerned in the great excess over the normal which was evident in the 2½-minute series: the number of cells entering mitosis per unit of time may be increased; or the time occupied by the process of mitosis may be increased; or there may be a combination of both of these. It would appear that, in long exposures, one or more of these factors is still acting, but that more permanent damage has been done to the cells, which, in the 30-minute exposure series, prevents mitosis from reaching the normal level again.

[1] *Proceedings of the Royal Society*, B, vol. cv, 1929.

THE SCIENTIFIC STUDY OF SEX PROBLEMS.

THE World League for Sexual Reform, which opened its third international congress in London on September 8th, has expressed its general aim in a resolution appealing to legislatures, the press, and the peoples of all countries to create a new legal and social attitude towards the sexual life of men and women, based on knowledge which has been acquired from the scientific investigation of sexual biology and psychology. It is perhaps inevitable that an organization which is frankly reformist in aim should include among the proposals it advocates some, at any rate, for which, in the present state of our knowledge, the scientific sanctions are not yet clearly established. It does not follow that such proposals are undesirable or unworthy of the sympathetic attention of enlightened men and women; but no one who has studied the specific aims of the league, as opposed merely to its general aim, can fail to observe that some of them, at any rate, are based on the uncertain foundation of sentiment rather than on the firm rock of science. Thus, the second among what are termed the ten "planks of the league's platform" is "the liberation of marriage (and especially divorce) from the present Church and State tyranny." It is not clear, even if the existence of such tyranny is conceded, why science should ally itself with one of the victims more firmly than with the other—why, in fact, divorce should be accorded a preferential treatment denied to marriage. A similar unaccountable discrimination is expressed in the sixth of the ten "planks," which enjoins "a rational attitude towards sexually abnormal persons, and especially towards homosexuals, both male and female." It is difficult to believe that the supporters of the league really wish society to adopt towards persons who, though sexually abnormal, are not homosexual, an attitude less rational than it is asked to adopt towards those whose abnormality consists of homosexuality; it may indeed be hoped that in this matter, as in the matter of marriage and divorce, the World League's views, whether one agrees with them or not, are more consistent than would appear from the way in which they have been expressed. It may be suggested that should the league decide to redraft the manifesto embodying its ideals and proposals it would do well to call to its help one or two of the many eminent men of letters whom it counts among its supporters. As might be expected, some of the problems discussed at the present congress—for example, birth control, abortion, sterilization, and the prevention of venereal disease—directly concern members of the medical profession; others—those relating to marriage, divorce, and prostitution, for example—concern them only indirectly, no more and no less than they concern other individuals who are mindful of the future development of our civilization. It is difficult, perhaps undesirable, to attempt to make a hard-and-fast demarcation between the subjects in the first category and those in the second. No consideration of the problems of birth control, sterilization, and abortion, for example, is complete which fails to take notice, not only of their medical, but also of their ethical and sociological aspects. The doctor, by virtue of his special training, is more qualified than others to judge of the medical grounds for the adoption of these expedients, and to work out the technical problems involved in their application; in relation to their social consequences his judgement has no more value than that of any other equally enlightened citizen. It may likewise be suggested that the problems of marriage and divorce, though they are mainly sociological and ethical, have also physiological and psychological aspects which no doctor may assume to lie wholly outside his province. It is clear from a study of the congress programme that its organizers have been fully alive to the danger of segregating the various subjects under consideration into the arbitrarily defined categories of medicine, sociology, ethics, and so forth. Medical men and women have contributed papers on the problems of marriage and divorce; lay persons have discussed various aspects of birth control, sterilization, and abortion. The congress will remain in session until September 14th. From some of the papers which have already been read it is clear that, whatever view may be held of its reformist aims, the World League for Sexual Reform is endeavouring on the whole to consider the difficult problems with which it is specially concerned in a scientific and commendably dispassionate spirit.

As we go to press we learn with regret that Mr. Charles Alexander Morton, emeritus professor of surgery in the University of Bristol, died at Zürich on September 7th, while on holiday. We hope to publish an obituary notice in an early issue.

THE POWER OF PERSONALITY.*

BY

SIR ARCHIBALD GARROD, K.C.M.G.,
D.M., LL.D., F.R.S.

TEN years ago, on the eve of Sir William Osler's seventieth birthday, there forgathered at the house of the Royal Society of Medicine a number of his pupils, friends, and colleagues, to present to him a "Festschrift"—two volumes of essays and papers written by them in his honour—a form of tribute rare in this country although not uncommon on the Continent. The occasion was marked by a charming speech by the late Sir Clifford Allbutt, his opposite number at Cambridge, and by Osler's no less felicitous reply. We who were present at that gathering little thought that the man whom we had met together to honour had less than six more months to live.

Even during Osler's lifetime a volume of excerpts culled from his writings by Dr. Camac, and entitled "Counsels and Ideals," had had so large a sale that four impressions had been exhausted, and a new edition, which has since appeared, was called for. Again, it has been my privilege to address an Osler Society in Oxford, and now the Osler Club in London; and I believe that such societies, founded to perpetuate his tradition and ideals, are not confined to this side of the Atlantic. If we ask to what we are to ascribe these so personal tributes, and a tradition held in so great honour, all who knew Osler will attribute them, without hesitation, to his outstanding personality.

The fact that, as I am told, few if any of the younger members of this club ever saw Osler in the flesh, or heard his voice, shows that the influence and tradition of such a personality outlives its possessor, and is capable of being transmitted in his writings and those of others. The prophet Elijah and Alfred the Great are still vivid realities, and, like them, Shakespeare is immortal. What, then, do we mean when we speak of the personality of a man or woman? Turning to the great Oxford Dictionary I find the following definition of the term, in the sense in which I am using it: "That quality, or assemblage of qualities, which makes a person what he is, as distinct from other persons—distinct personal or individual character, especially when of a marked or notable kind." Obviously, in this sense, every human being has his personality. Each one of us differs from his fellows, not only in bodily structure and the proteins which enter into his composition, but apart from, or rather in consequence of, such individualities, men differ from their fellows still more obviously in mental outlook, character, and ability.

Amidst the great crowd of ordinary people, all different but none outstanding, we distinguish some individuals of unusual mental or moral stature, or personality, who owe their distinction less to any single quality than to an *assemblage* of such, as the dictionary suggests. These are the ferment folk who get things done. Surely it is hardly necessary to emphasize the part which such personality has played in the story of human progress, in the history of civilization. It assumes various aspects: is manifested in the orator who sways a crowd; in the poet who voices the soul of a people; in the musician who, like Rouget de Lisle, produces a tune which sets history working; in great warriors, such as Hannibal and Napoleon, who have made and led unconquerable armies; in great discoverers and thinkers who have changed the outlook of the human race. Yet it is not the same thing as genius. The brilliant discoverer, artist, or writer may lack personality; whereas men of far lesser gifts may, in virtue of their personalities, be leaders of men, and may be, as it were, surrounded by magnetic fields. I, at least, believe that individual stimulus and effort have played the largest part in history, and that progress is more often due to men of great personality than to the collective shove of multitudes of ordinary men.

Yet it must be remembered that each one of us has his personality, for good or ill; each one influences his fellows far more than he usually realizes, and the movements of a crowd are the sum of those of its individual members, not merely of the cogs or teeth of a machine. There is no level at which personality begins, no sharp line between Socrates, Julius Caesar, and the tramp upon the high road, only a series of imperceptible gradations. Happily for us, we do not recognize the repercussions of our personalities as we walk through life, nor the extent to which even the most insignificant of us influences his neighbours. Did we do so we should be tempted to take refuge in a Trappist monastery.

People of outstanding personality, the ferment folk, differ widely amongst themselves, and various factors go to their making. Ability, I take it, they must possess, and wisdom; the gift of expression, a clear brain, a ready tongue. A sense of humour, one of Nature's choicest gifts, can hardly be dispensed with, and, among the essentials also, human sympathy and interest in the work and aims of others.

Each one of us, when he casts his thoughts backwards over his own life, recalls a few people who have influenced him powerfully either for good or evil; but it is upon the former that our memory likes to dwell. We recall the schoolmaster who awakened our interest in what has been our life's work; he who by a word of encouragement spoken in good season helped to give us confidence, and showed us that one person at least believed that there was something in us. Another may have succeeded in interesting us in subjects for which we had no aptitude—classics perhaps—and who seems to walk beside us when we tread the streets of Athens or of Rome. No doubt as we grow older these people tend to grow in stature in our memory, but they undoubtedly possessed striking personality, and sowed a grain of mustard seed which has produced a tree. Any man who teaches others cannot be a really good teacher unless he exerts some such influence; the lecturer must interest himself as well as his hearers. Probably each one of the elders of us has been told, by some former pupil, that he has never forgotten something which we said many years ago. We hope that he will recall one of our choice but forgotten aphorisms, but it usually turns out to be a platitude to which he has clung so long.

Apart from its personal magnetism, a striking personality may be reflected and, so to speak, crystallized by a great writer or biographer. How else is it that we so clearly recognize that which distinguishes Elijah from Elisha, and Queen Elizabeth from King Henry VII. Plato has been able to hand down to all time his own mental picture of the personality of Socrates, and Boswell reflects for us that of Samuel Johnson.

Personality in Medicine.

But I want to confine my remarks to our own field of work, to medicine and the sciences upon which it rests, and to consider how men of outstanding personality have influenced, and will influence, the progress of our science and art. It seems to me that my subject falls under three main heads, but that the categories overlap, and one man may come into several of the groups.

First let me speak of the men of "light and leading" who, like the Pied Piper of Hamelin, pipe a tune which others cannot but follow. Human sympathy and unselfishness are their chief weapons, and they promote in every way the brotherhood of their profession. Behind them their colleagues fall into line, in associations, societies, and less formal comings together; and around them they gather a group of disciples, who, going forth into the world, carry on their traditions and broadcast their teaching. A man may be a great teacher and yet be devoid of this power, and it may be wholly wanting in a great investigator.

Osler's outstanding personality was of this kind. In any international gathering he would draw around him friends from many nations; he did more than any of his contemporaries to promote the brotherhood of medicine. He was no detractor from his fellows, and was unwilling to listen to detraction—his power of turning the conversation away from such talk was celebrated. Many a younger man has gained encouragement from a postcard or telegram, which arrived opportunely, from wherever Osler

* An address delivered at the annual meeting of the Osler Club, on July 12th, 1929.

might be, to give a pat on the back to an aspiring author, or to congratulate the recipient of some distinction or step of promotion. His praise or encouragement was bestowed in delicate touches, not in gross daubs; and no one knew better how to convey the apt word of sympathy. He was eminently a man who liked to be liked.

Yet I am far from wanting to do him the injustice of drawing a picture of perfection. Aristides was not popular, nor, I suspect, was he the possessor of a great personality. Osler was very human, and his weaknesses added to his attraction. His very unwillingness to say "No" sometimes got him into trouble, as when he signed leaflets both for and against the abolition of compulsory Greek. His humour was impish, and at times mischievous; and his *alter ego*, Egerton Y. Davis (who was no other than Osler in impish mood), had many of the characteristics of Til Eulenspiegel. So troublesome did he become to his inventor that he had to be drowned in the Lachine Rapids in 1884, and his body was never recovered; but, oddly enough, he occasionally signed a note in the Oxford days, and once a "fake" examination paper. I am afraid the collected writings of Egerton Y. Davis have not been republished, but some are included in the catalogue of the library. On one occasion Osler spoke of himself as the possessor of a wild and wagging tongue which often got him into trouble, and we recall "Too old at forty."

His personality permeates his writings, and especially those lectures and addresses from which Dr. Camac's quoted passages are chiefly derived. *The Autocrat at the Breakfast Table* is included in Osler's medical student's library, and there is no little affinity in the personalities of the two men—Osler and Oliver Wendell Holmes—the same happy turn of phrase, the same broad humanity. We have known men who were as good teachers and as great physicians as Osler, and some equally learned in the standpoint of ancient medicine—men with Hippocratic minds—but who, for lack of that subtle quality which we call charm, and which is one of the manifestations of personality, could never have sounded that happy note which the children of Hamelin could not but follow.

I do not propose to dwell on the part played by the personality of the medical man in his relations with his patients. It is no less potent, but is much less far-reaching The sympathetic touch, the cheery word, which must not imply a too sanguine optimism; the tactful conveyance of unwelcome truths, and an underlying sympathy with, and understanding of, his fellow man, gain him an influence over his patient which may turn the scale in a critical time. Without such qualities a man with equal knowledge and no less skill may be comparatively powerless to help.

The Clinical Teacher.

There is no one whose personality exerts more influence than does that of the teacher. That is true of medicine as of any other branch of study, and in that kind of clinical teaching which originated in this country, and is still carried out in the English schools, the opportunities for personal influence are specially great. The daily meeting, at the bedsides of the patients, of the teacher and his small band of pupils who share in the work of the clinic, brings teacher and taught into peculiarly close contact, much closer than that of a lecturer and his audience.

This feature of English clinical teaching has been the outcome of a gradual development. Our ancient universities, Oxford and Cambridge, which were the only English universities down to the thirties of the last century, have possessed Regius Professors of Medicine, or Physic, since the reign of Henry VIII, but no hospitals existed in those towns before the eighteenth century. Their professors expounded the writings of Hippocrates and Galen, but could impart no practical teaching in their subject. For such teaching their pupils had to go elsewhere—to Padua at first, as the great school of anatomy, and later to Leyden, where medicine was first taught at the bedside by university professors—or else acquired their experience as apprentices to practitioners. Later they found their way to Edinburgh, which a century ago was undoubtedly the first medical school of these islands, or "walked" the London hospitals for a time. When at length hospitals were founded, first at Cambridge and afterwards in Oxford, there were teachers ready to teach in them, but the habit of going afield for such studies had become firmly established, and has been maintained.

Into almost all our modern English universities, on the other hand, a pre-existent medical school has been incorporated. In none of our universities has a medical school been initiated *de novo*, having attached to it a new hospital, free from the many restraints of vested interests to hamper in the choice of a staff. In this city the early medical students were apprenticed to the surgeons or apothecaries of the hospitals, and the clerks and dressers of to-day are the lineal descendants of those apprentices. Even in my own student days at St. Bartholomew's the dressers had to pay extra fees to the surgeons for whom they dressed, but not to the physicians for whom they clerked—a survival of the apprenticeship fees. A century ago there were many surgical students at the London hospitals, but students of medicine were few, being for the most part graduates of Oxford or Cambridge, or Edinburgh graduates who aspired to practise as physicians. As the number of clinical pupils increased some provision had to be made for teaching them other than clinical subjects. Lecturers, who were almost always members of the hospital staffs, were appointed in anatomy, chemistry, and, later, physiology, but the same lecturer often dealt with several subjects. So the private schools of anatomy gradually died out, and there grew up a number of medical schools, each attached to a large hospital. When University College was founded each professor dealt with only one subject in his lectures, but otherwise the original system was continued.

In Continental countries, on the other hand, the teaching of medical subjects has been in the hands of the universities, and was, and is, imparted by university professors, who are heads of clinics embracing wards and laboratories, and served by assistants who are often highly trained men. Until comparatively recently the German medical student had little direct contact with patients, save in the professors' demonstrations, until his examinations were passed, and had no part in the care and treatment of them in the wards. In this country, on the other hand, until comparatively recent years, the majority of our students had not the advantage of university training.

Under either system the personality of the teacher counts for much, for each student is, to some extent, a fellow-worker with his chief, and his work is shaped by his teacher's views. He learns from him how to approach a case, how to observe essential points, and can watch his treatment and its effects. He learns, too, courtesy to, and consideration for, the patient. It is not only the *art* of medicine which he learns. Remember that medical men in active practice built up the medical sciences, and, indeed, that they have played very large parts in the advancement of the sciences in general.

One need only recall such men as William Gilbert, President of the Royal College of Physicians, and father of magnetic science; Thomas Young, one of the greatest men of science which this country has produced, who played a large part alike in the foundation of the undulatory theory of light and in the deciphering of the Egyptian hieroglyphics. There is a memorial tablet on the house in which he lived and practised in Welbeck Street. Until recently the great advances in medicine were made by men in practice. Think of Bright and Addison and William Jenner. What a stimulating experience it must have been to clerk for Addison, or to have been his house-physician, for he was a great teacher as well as an investigator, and beloved by his pupils, as one may learn from Sir William Hale-White's memoir of him in the *Guy's Hospital Reports*. Nor is the race of such workers extinct. In the daily intercourse of the wards there is a constant passage of ideas from teacher to pupil, and indeed from pupil to teacher, in addition to what may be called the atmosphere of the hospital, that floating mass of knowledge, not to be found in textbooks, which reflects the collective experience of generations of teachers and learners. It differs from school to school, and those who work in special hospitals most fully recognize its importance.

On the other hand, the professor in a German university can exert a profound influence upon the students who attend his clinic, upon his assistants, and upon those who come from outside to work with him in the clinic. The daily clinical lecture is usually illustrated in every possible way which may add to its efficiency, whether by the cinematograph or by a cracked pot. The assistants who are charged with the preparations may have many hours of strenuous work in getting ready for the next morning's clinic.

From among the assistants are chosen the future professors of that or other universities. It is clear that special qualities are needed by the heads of such clinics, whether they be whole-time men, like the heads of our units in London, or, like most Continental professors, not debarred from practice, and usually with private wards under their care. They should be inspiring teachers, should be imbued with the investigator's spirit, should know their subject thoroughly, and should be versed alike in the clinical methods and those of the laboratory, which are of so great value in medicine. Anyone who believes that clinical observation is played out, and that there is no science of clinical medicine, is out of place at the head of a clinic.

I have dwelt at some length upon the power of personality in clinical teaching, because it seems to most of us who knew him that Osler's greatest achievement was the conception and establishment of the medical clinic at Johns Hopkins. There he was given a free hand, a new hospital with no established traditions to be broken through, and no existing staff to be replaced. He had, too, the inestimable advantage of the backing and advice of exceptional colleagues, such as Welsh, Halsted, and Kelly. He followed no definite model, but took what seemed to him best in the English and Continental systems, and, above all, made sure that students and teachers alike should take their respective shares in the work of the clinic and care of the patients. The assistants whom he trained have spread the light widely, and I think I need not fear contradiction if I say that from Osler's clinic at Johns Hopkins there has gone forth an influence which has transformed medical education in the United States and in Canada, and has had repercussions upon this side of the Atlantic also.

As you know well, there are widely different methods of bedside teaching, even in a single medical school. There is a method which has a strong appeal to many students, and which may be called the tabulation method. Its appeal is like that of the cram-book, and it calls for no personality in the teacher. I remember going round once with a distinguished physician, long since dead, who had a considerable reputation as a teacher. At the bedside of a patient admitted for haematemesis the clinical clerks were questioned as to the causes of that morbid event, and twenty-eight causes in all were elicited, ending with swallowed knives and forks. In that way it is possible to become acquainted with many facts, but not to know them. Nothing could be further removed from Osler's method. When a case was under discussion in his clinic, not only were the signs and symptoms noted and the diagnosis discussed, but also the history of our knowledge of the malady, and even some points in the life of the man who first described it. If the case were one of typhoid fever, some of the students would be set tasks to be carried out before the next meeting of the class: one to look up Jenner's original papers on the differentiation of the malady, another to compare the symptoms observed with those recorded on a table of such cases seen in the clinic during the year. Osler held unwaveringly to the conviction that clinical medicine must rest upon a solid basis of morbid anatomy, and that the older as well as the most modern diagnostic methods should be applied wherever possible; and he looked upon the medicine of to-day against a background of its history.

He was so deeply interested in the subjects of which he spoke that his students could not escape the infection of his enthusiasm. All the time he was noting any unfamiliar congeries of signs, and from time to time there came from his pen descriptions of unrecognized, or partly recognized, syndromes—polycythaemia with enlarged spleen, hereditary telangiectases with haemorrhages, the visceral complications of the erythema group, and the like. Moreover, through his textbook and other writings he taught and communicated his enthusiasm to thousands who never heard his voice. Yet, withal, he was not a great man of science, nor, I would venture to suggest, one of the greatest of physicians; but because of the appeal of his personality, and the ferment influence which he exerted, his is one of the greatest figures of Anglo-Saxon medicine, and the medicine of to-day is much greater because of him. Unquestionably he was a great leader, a great teacher, and had a great belief in his fellow men.

Personality in Research.

There is yet another aspect of my subject, which I have left to the last, by no means because it is unimportant, but rather because of its immense importance. The great investigator may plough a lonely furrow, and have little personal contact with his fellow men, and yet his writings and the results which he obtains, his discoveries, may change the whole course of human thought. There are other investigators who gather around them, as a magnet does iron filings, men who draw inspiration from them, to whom they suggest lines of research, and whom they restrain from wasting their efforts by exploring blind alleys; this last a very important function. These *men* are the born professors. In these days, when the word research has degenerated to the level of jargon, we need to remember that it is not every man's *métier*. There are men of high attainments, excellent teachers perhaps, *who are what Osler called transmitters, not creators, nor* even transmuters, to use another of his terms. In another class are those who, although they do not tend to embark upon investigation on their own initiative, are well fitted to carry out original work under guidance. Men of that class are more fully utilized on the Continent than in our country, and they contribute largely to the scientific output of Continental clinics. Such a man occasionally figures as joint author of a classical monograph, but may never again appear in the *Index Medicus*. Such men far outnumber the primary investigators, but they do not readily find places in our medical scheme. We do not need to fuss about the primary investigator, he cannot help trying to find out; but his output will be greatly increased if he be given opportunities of stimulating and training a group of secondary workers. Team work calls for someone to drive the team, otherwise it tends to become herd work.

Whether, given the opportunity, a man shall become a successful professor depends largely upon his personality; on his power of infecting others with his own enthusiasm; his reactions to his fellow men and theirs to him. For research work calls for perseverance in face of discouragement; equanimity when weeks or months of patient work leads to nothing, insight to interpret results, ingenuity in devising methods, knowledge, and judgement. In the words of Ecclesiasticus, it is only when Wisdom has walked with him in crooked ways, and has tormented him with her discipline, that she returns unto the investigator the straight way, and shows him her secrets. The arduous nature of the path adds to the pleasure of discovery. Probably there is no greater pleasure open to man than that derived from the discovery of some new fact, even a very little one; or from the finding of the key which unlocks some unexplored chamber in the house of knowledge, and the finder delights to show his find to kindred minds which share his enthusiasm.

I am conscious of the fact that this discourse of mine has no moral. It would be useless for me to exhort you to do your best to acquire outstanding personality—such a thing cometh not by seeking; the assemblage of qualities which constitute it are inborn, inherent in the chromosomes from which its possessor springs. Many ancestors have contributed stones to the building. To one is owing the mental ability and clearness of vision, to another the gift of speech or writing, to another the sympathetic outlook, to yet another the sense of humour. All the ingredients need to be judiciously mixed and well balanced

if a great personality is to emerge. It is judicious blending which produces the best results.

Yet is there not a moral after all? For each one of us has his personality such as it is, and it behoves him to make the best of it. It is within our power to control, to some extent, the factors of our personality, or at least to keep in the background those which please us least. But yet it is not by concentrating our attention upon our own qualities that we shall learn to lead our fellow men.

THE STATE OF THE PUBLIC HEALTH.

SIR GEORGE NEWMAN'S REPORT FOR 1928.

[SECOND (CONCLUDING) NOTICE.]

General Epidemiology.

DURING the year under review the outstanding epidemiological events in England and Wales have been the continued prevalence of small-pox, an unusually large number of scarlet fever notifications, and, during the winter of 1928–29, the most extensive epidemic of influenza since 1918–19. While the number of cases of small-pox was 2,367 less than in 1927 (12,420 as against 14,787), the number of deaths rose from 47 to 53. The usual relation between the vaccinal condition of the patients and the incidence of small-pox has been maintained, a table compiled from information supplied by medical officers of health and others showing that only five vaccinated persons and no fewer than 532 unvaccinated under 15 years of age contracted the disease. Even in the prevailing mild form of small-pox cases of greater severity have occasionally been encountered, characterized by pronounced prodromal symptoms—pains, vomiting, marked pyrexia, prostration, and delirium. The notifications of scarlet fever cases amounted to 102,611, as compared with 84,450 during 1927; the number of deaths registered, on the other hand, was only 580, as compared with 579 in the previous year. Since 1924 the incidence of diphtheria has risen steadily from 41,980 notified cases to 61,134. During the year there were 3,191 deaths from this cause, representing a case mortality of 5.2 per cent.; for scarlet fever the parallel figure is 0.56. Measles, next to whooping-cough the most fatal infectious disease of childhood, accounted for 4,302 deaths; deaths from whooping-cough, however, showed a decline, being 2,976, as against 3,681 in 1927. The figures for the enteric fevers differ little from those of last year. Sir George Newman points out that while gross sanitary defects are becoming less and less responsible for the spread of these diseases, special danger now lurks in the fact that modern methods of wholesale distribution of milk and foodstuffs make it extremely difficult to trace the distributing agents of the infection. In general, there has been a decline in the incidence of the infectious diseases which attack the nervous system. Notifications of acute poliomyelitis decreased from 801 to 452, though the number of deaths registered—namely, 112—remained the same. Similarly, there has been a decline both in the number of case notifications and of registered deaths in respect of encephalitis lethargica; and the cerebro-spinal fever notifications, notwithstanding their rise towards the end of the 1928–29 winter, show, in the Chief Medical Officer's view, no cause for disquietude. With regard to the nervous complications following vaccinia, Sir George Newman points out that it is not correct to assume that these may never follow primary vaccination of infancy; it is, however, true to say that the larger proportion of cases of post-vaccinal nervous disease seem to have occurred after primary vaccination of older children.

Gradually more precise information is being accumulated about the value of various methods of immunization against diphtheria, scarlet fever, and measles. Experience has strengthened belief in the value of toxoid-antitoxin in the prophylaxis of diphtheria, but has tended to show that better results are obtained if an interval of two or three weeks is allowed between the injections. Scarlet fever antitoxin appears to reduce the tendency to complications, and consequently to shorten the average duration of stay in hospital. Active immunization with toxin has proved effective in protecting staffs of hospitals, but the number of doses required makes its general adoption impracticable. Serums prepared from organisms alleged to be responsible for the causation of measles have proved valueless in the prevention or treatment of the disease. Intramuscular injection of 3 to 5 c.cm. of convalescent serum, however, if made before the sixth day after exposure to infection, will almost invariably confer complete protection for about three weeks; given later it usually modifies the attack, and thus has the advantage of establishing permanent immunity at comparatively small risk. The Chief Medical Officer expresses the hope that more use will be made of convalescent serum, and that local authorities who are able to collect a supply will make it available for young children at home as well as in institutions. Collection, he points out, is merely a matter of administration, only a few adult donors being required to meet the needs of a small community.

Influenza.

Having surveyed briefly the occurrences of influenza in England and Wales subsequent to the great pandemic of 1918–19, Sir George Newman proceeds to describe the epidemic of 1928–29, and recalls the interesting fact that, as the prevalence of respiratory disease during the last months of 1928 was low, and there was no indication of an increased incidence of epidemic nervous diseases, there was little to suggest the approach of epidemic influenza. On the other hand, disquieting news from America made it desirable in the first week of January to draw the attention of local authorities to the possibility of an outbreak of more than usual magnitude. The situation completely changed about the middle of January, 1929, and from then to the end of March an epidemic prevailed more serious than any experienced since that of 1918–19. The increase in mortality returns, gradual during December and early January, became abrupt at the end of the latter month, but thereafter, week by week, the disease gained ground until early in March the maximum weekly mortality of 2,183 was reached; from this date the prevalence of the disease declined rapidly and the fall in the death returns was progressive and uninterrupted. In the first week of December, 1928, the death rate from influenza per 1,000 of population stood at 0.16; by the last week of February it had risen to 5.78. In London, which suffered less than other towns, the maximum reached was 5.35. The Midlands sustained the brunt of the epidemic, their influenza death rate in the first week of March being 9.67 per 1,000; in the North, attacked less severely, the climax was 6.26 per 1,000. Wales escaped most lightly of all, with the maximum death rate of 2.74. The climax of the epidemic was not reached at the same time in all parts of the country; nor did the disease always develop coincidently in neighbouring large towns. From figures supplied by the Registrar-General it would seem that the epidemic moved in two main waves, one extending northwards from Greater London, and an earlier one proceeding southwards from Glasgow. Generally speaking, the chief mortality affected those of 65 and over.

Having described the clinical manifestations of influenza of recent years, including those of the 1928–29 epidemic—noting incidentally that the severity and clinical characters of the disease differed in various regions of the country, and that lobar pneumonia occurred with unusual frequency in London—Sir George Newman proceeds to discuss the occurrence of rashes in influenza, pointing out that as it is not always appreciated that these may appear—their description, indeed, being omitted from many textbooks in medicine—their presence may give rise to errors of diagnosis. He suggests that during an epidemic the general practitioner should bear in mind the possibility of such rashes, and consult with the medical officer of health on any doubtful case.

Influenza being a disease spread by personal contact and droplet infection, it might appear that its prevention could be attained by the administrative enforcement of strict isolation. In fact, the epidemiological problem is not that of a disease like plague or small-pox, where the isolation of the infected is equivalent to a separation of the diseased from the healthy. Not only is the causal organism of influenza not definitely established, but no

criterion is available for differentiating the mild case of respiratory catarrh from one of influenza. Furthermore, the subjects of a mild attack are able to continue their ordinary vocations, and it is possible also that there may be healthy carriers of the influenza virus. Even if the attempt to enforce isolation were made, many sources of infection would still slip through the administrative net and maintain an epidemic. Sir George Newman, after some critical commentary on various preventive measures which have been proposed, comes down heavily on the side of common sense and simplicity, and offers as his chief counsel the need, when influenza is prevalent, to invite the public to obey the ordinary rules of personal hygiene. "Persons who practise the rules of health," he concludes, "keep themselves fit, and take all possible care to avoid 'droplet' infection from mouth or nose, are likely to preserve resisting powers which, if they do not carry them unscathed throughout the epidemic, will moderate the intensity of their symptoms and the liability to pulmonary complications if the disease is eventually contracted."

Tuberculosis.

Though notification of tuberculosis is admittedly becoming more effective, Sir George Newman has, as in previous years, to deplore the fact that notifications are far from complete, and that frequently they are made too late to enable effective help to be given to the sufferers. In 1928, out of 77,881 total fresh cases coming to the knowledge of the health authorities, information was not received until after the death of the patient with regard to no fewer than 4,252, a figure which represents 11.6 per cent. of the total deaths from tuberculosis. It will be recalled that, in commenting on the slight increase in deaths from tuberculosis in 1927, the Chief Medical Officer suggested that it would be found not to affect seriously the steady downward trend of the death rate. The figures for 1928 confirm his view, the deaths both from pulmonary and non-pulmonary tuberculosis being not only lower than in 1927, but lower than in any previous year. Since 1911 the gross death rate from pulmonary tuberculosis in males has fallen from 1,233 per million to 879, in females from 900 to 641; even more striking is the reduction in non-pulmonary tuberculosis, the male death rate having fallen from 436 to 188, and the female from 378 to 159. These are impressive figures, and one cannot but agree with the Chief Medical Officer that they afford encouragement in proceeding with developments of the various measures to combat this disease. Just now the moment to consider such developments is particularly opportune, as under the Local Government Act of 1929 local authorities have the opportunity of revising and enlarging their tuberculosis schemes. Under the Act medical officers of local authorities will have to consider how the institutions taken over from Poor Law authorities can be used to the best advantage, and to what extent hospital provision needs to be supplemented. It is suggested that the tuberculosis dispensaries might perhaps be suitably worked in the same premises as the out-patient departments which many local authorities will no doubt provide in connexion with the hospitals in their charge, and that in some areas these out-patient departments may become general health centres for the various services provided by the local authority.

Since the publication of last year's annual report a considerable amount of work has been done on the subject of immunization by B.C.G., Professor Calmette having presented a lengthy statement at an international conference held at Paris in October, 1928. Difficulties in the investigation of B.C.G. are the comparative smallness of the number of cases studied, the lack of adequate control observations, the uncertainty whether its administration may not even give rise to the disease against which protection is desired, and the disharmony between the experimental findings of different workers. Sir George Newman concludes that in this country the question must be regarded as still *sub judice*, and that in so serious a matter as the administration of a living vaccine to human beings confirmatory investigations are necessarily required.

Cancer.

In the year under review there was again an increase in the recorded mortality rate from cancer, the total number of deaths certified as due to this cause being 56,253, giving a rate of 1,425 per million persons living. Having considered some of the problems relating to the proportional frequency of cancer in different sites of the body, and of the so-called "latent" period of cancer, the Chief Medical Officer proceeds to detail the findings of the Departmental Committee, of which terms of reference were "to consider available information with regard to the causation, prevalence, and treatment of cancer, and to advise as to the best method of utilizing the resources of the Ministry for the study and investigation of these problems." He concludes this section of the report with an analysis of the principles of radium therapy in cancer, and discusses certain considerations—most of which have become familiar to those who have followed the recent literature of the subject—which should be taken into account in deciding the future developments of radiotherapy in this country. In brief, the guiding principles appear to be the need to keep radium in action as constantly as possible; to maintain it in different quantities in containers of various sizes and shapes; to bring to suitable centres, staffed by surgical and radiological specialists, an adequate supply of patients; to train attendants for skilled service and in measures for their own protection; and to ensure from the beginning of treatment the fullest co-operation between the radiotherapist and the surgeon in charge of the case.

General Considerations.

The remainder of the report embodies sections on venereal disease; the relation of food to health and disease; the work of the Ministry's pathological laboratory; and such varied subjects as acute rheumatism, undulant fever, accommodation for the sick at public schools, swimming baths hygiene, rural water supplies, artificial light treatment, port sanitary control, international health, and so forth. Of special interest are the survey of the working of various rheumatism supervisory centres, the discussion on the relation between undulant fever and contagious abortion, and the report on the health of the population in mining areas, which has already been summarized and discussed in our columns on March 2nd (p. 415). A few minor textual errors appear in the report, the data in corresponding with those given in the tables. Taking it as a whole, however, the report throughout is admirably written and permeated with an idealism which is all the more inspiring because there is nothing Utopian about it. Sir George Newman moves his readers to wake up and dream!

Belgium.

[FROM AN OCCASIONAL CORRESPONDENT.]

Children and Cinema Performances.

More and more it is becoming evident that the cinema has an evil influence on the education of children, and Dr. Rouvroy, the medical superintendent of an institution for abnormal children, who has been able to investigate the effects of cinematograph performances on three types of children—namely, the abnormal, the subnormal, and the highly strung—has called attention in the *Revue Internationale de l'Enfance* to the danger in this connexion. The results are said to be worse than those brought about by harmful books or pictures, and no real value can, he thinks, be attached to the operation of a censorship or the imposition of an age limit. Even the best films for adults contain scenes of violence and crime; they may be of a highly suggestive type, and they have an intense effect on the sensitive mind of the child. In particular, films of the propaganda kind tend to advertise the vice they are supposed to condemn. Moreover, the intensity with which the child's attention is gripped by the film story is a cause of fatigue. Thus, a performance lasting two hours, including ten two-minute intervals, involves an expenditure of 20 per cent. of the physical energy—twice that involved in the ordinary school day; the effect is still greater in the case of less healthy or nervous children. The stereotyped gestures of the actors make a remarkably deep impression on the subconsciousness of the

spectator; a whole category of physically and mentally subnormal children (often considerably under the age specified in the regulations) are affected by such gestures, and reproduce them automatically in moments of strain. Moreover, Dr. Rouvroy remarks, subnormal children are more numerous than is generally thought.

The Campaign against Diphtheria.

In the province of Luxembourg Drs. Lomry and Duble have undertaken an extensive study of the periods before and after the introduction of inoculation against diphtheria. They conclude that the practice of treating "carriers," which before the employment of inoculation was the principal line of anti-diphtherial prophylaxis, and which retained this distinction during the time when toxin-antitoxin was being used, has now become a secondary and accessory measure of hardly any value since the discovery of anatoxin. Although its utility has not yet completely vanished, inasmuch as inoculation is still not general, the search for bacillary carriers will be limited to the contacts of the patients in their homes and schools, and the active treatment of such persons will be confined to those in whom direct examination has revealed the presence of bacilli in large numbers. The two investigators add that the toxin-antitoxin preparations ought to be entirely abandoned, because they are essentially dangerous; they should be replaced by inoculation with Ramon's antitoxin, which is highly effective and quite devoid of risk. The administration of anatoxin, they add, should become as general in schools as is vaccination against small-pox, and as common in the home as anti-typhoid inoculation.

An Association of Belgian Surgeons.

An association has just come into being which has as its first objective the defence of the professional interests of surgeons; the president is Dr. de Beule. It appears as a "Union professionnelle reconnue," the legal details of which have been drafted by a provisional committee, to federate those surgeons who are more particularly concerned with matters of social insurance, as, for example, the presidents of the professional associations dealing with accidents in industry, and specialists in urology, ophthalmology, oto-rhino-laryngology, and gynaecology. As soon as the necessary constitution and rules have been drawn up a second general meeting will be held to elect members of the governing committee and to authorize the regulations.

Beer and Cancer.

In a Belgian journal associated with the brewing industry there is published an intriguing study of the influence of beer on cancer. The question was recently asked at the Congress of the General Federation of Brewers whether beer could in any definite way protect against this disease. This suggestion was based upon the fact that cancer never appeared among the causes of death of young employees in the brewing industry. Support was given to this view by Dr. Ducamp, head of the public health department in Lille, after he had verified the statistics of the last ten years. An investigation is actually in progress throughout France with a view to establishing the accuracy of the hypothesis. The congress voted in favour of a similar inquiry being undertaken in Belgium. Certain Belgian manufacturers who are well known, not only for their efficiency, but also for the scientific care which characterizes their work, think that the fact is certainly established in respect of the unfiltered beers—that is to say, those which still contain certain ferments.

Industrial Diseases.

A catalogue of those diseases which are to be classed as industrial has just been issued by a Royal decree. The first clause in this list deals with the various forms of poisoning due to lead, its alloys, and mixtures containing it, and with any direct sequels of such poisoning. The industrial processes thus concerned are as follows: the handling of minerals of which lead is a component, including the lead dusts in factories dealing with zinc; processes entailing the employment of zinc and lead; the production of amalgams of these two metals; lead rolling; the extraction of silver from argentiferous lead ores; the manufacture of articles composed of lead or its alloys, and their manipulation; the preparation of lead compounds; the construction and repair of accumulators; the production and use of lead-containing enamels; polishing processes entailing the employment of lead filings or putties; operations involving the manufacture or handling of glazes, gums, and pigments containing lead; and all preparations which are liable to give off plumberiferous dusts or gases. The second clause relates to poisoning due to mercury, including its amalgams and compounds, and with the direct sequels of such interference with health. This clause affects industries necessitating the handling of minerals containing this metal; the preparation of mercury compounds; the manufacture of certain kinds of measures and laboratory apparatus; processes involved in hat making and the use of felts; fire glazing; the construction of mercury vacuum pumps and of explosives containing this metal; and the general manipulation of mercury and its amalgams. The third clause deals with anthrax resulting from the handling of animals which may transmit this infection.

England and Wales.

Malarial Treatment of General Paralysis of the Insane.

IN his report for the year 1928 Dr. R. Eager, medical superintendent of the Devon Mental Hospital, records the results obtained in the malarial treatment of 15 patients—13 male and 2 female—suffering from general paralysis of the insane. Of the 15 patients, 7 were infected directly by mosquitos supplied by the Ministry of Health, and 8 with blood from patients already under treatment; 3 patients became well enough to be discharged to their homes, 2 improved mentally and physically but not sufficiently to justify their discharge, 2 showed physical but not much mental improvement, 4 remained very much as they were, and 4 died. One of the patients died before the treatment had been completed, and at the post-mortem examination his heart was found to be in a state of fatty degeneration. Of those who improved under the treatment one patient, after the treatment had been completed, sustained a severe abscess in the thigh, which was followed by an attack of acute pneumonia; notwithstanding the supervention of an empyema which had to be drained, he made a good recovery. Dr. Eager states that since 1925 30 male and 4 female patients suffering from general paralysis of the insane have received systematic malarial treatment at the Devon Mental Hospital. Of these patients 7 (all males) have been discharged and so far have not returned. They have been re-examined periodically at intervals of about six months at the clinic in Exeter, and all of them, when last seen, were well. Up to the present, attention has been concentrated exclusively on the malarial treatment, the additional administration of arsenical preparations having been deliberately withheld in order to allow of a just estimation of the value of the malarial treatment alone. In 1925, when the treatment was first started, it was withheld from three patients, who were then used as controls. One of these patients is dead, one is bedridden, and the third appears to be suffering from cerebral syphilis rather than from a typical general paralysis. Dr. Eager believes that the results so far obtained by him and his colleagues in the malarial treatment of general paralysis justify them in going on with it, especially in view of the fact that in the past all cases of this disease ended fatally. He now proposes to treat one group of patients with malaria only, and one with a combination of malaria and an arsenical preparation, and to compare the results. In this connexion it is interesting to note that, as was pointed out by Dr. T. Saxty Good at a discussion under the auspices of the Royal Medico-Psychological Association, experience suggests that, while patients with general paralysis are treated more safely by malaria than by anti-syphilitic injections, after malarial treatment has been completed these injections might produce a cure.

Order of St. John of Jerusalem: Priory for Wales.

Sir Herbert D. W. Lewis, K.B.E., Commissioner for Wales of the Order of the Hospital of St. John of Jerusalem, in his annual report for the year 1928, gives an interesting account of the steady progress made by the Welsh priory during that period. This priory is primarily the Welsh national ambulance organization, and its work may be divided into two sections—the educational and the practical. So far as educational work is concerned, Sir Herbert points out that the number of people receiving instruction in first aid, home nursing, and allied subjects has increased from over 3,000 in the year 1921 to nearly 12,000 in 1928; facilities are provided in every county for the public to receive this training, and it is impossible to overestimate the value of such work as this in the fight against disease. On the practical side, similar progress has been made, and the brigade in Wales has now nearly 9,000 members, all of them voluntary workers receiving neither payment nor reward for their time and services; in 1920 the brigade personnel numbered 5,000. The members provide their own equipment, and very often replenish their haversacks with ambulance dressings at their own expense. The usual forms of public duty include the attendance of uniformed members at various public functions, such as sports meetings, performances at theatres and cinemas, and all occasions where crowds are likely to assemble; patrol duty is undertaken at seaside promenades, and on the main roads throughout the country at holiday times and week-ends. Wales is also contributing its quota to the Royal Naval Auxiliary Sick Berth Reserve and to the Military Hospitals Reserve, both of which are supplementary to the regular medical services of the Crown forces. Details are given of the extensive motor ambulance transport service set up by the priory, and also of a particularly useful form of charitable work—the provision of medical comforts depots. There are thirty-five of these, from which the public may obtain on loan, at nominal charges, medical requisites, invalid equipment, and comforts for the sick-room. The report summarizes many other branches of voluntary work in which the priory is engaged, and a description is added of the activities of the county centres and sub-districts during the year. The record throughout is one of sustained progress, and the only regret expressed is that further extension of the priory's work is hampered at present by lack of funds.

The Park Hospital, Davyhulme.

The Park Hospital, Davyhulme, situated about six miles south-east of Manchester, was officially opened by Princess Mary in June. The buildings are grouped on either side of a main corridor 220 yards long, running east and west. On the southern side of the main corridor are the ward blocks, running north and south, also a part of the administration block. North of the main corridor are the children's ward, the maternity block, the main kitchen, the laundry, workshop, and boilerhouse. The twelve main wards are arranged in six blocks, each with a ground floor and first floor; each ward has accommodation for thirty-one patients. The main section of the ward has twenty-four beds, of which six are placed in cubicles, and there are also seven beds for private patients. There is one ward of three beds, and two wards with two beds each. On the south side of each main ward are spacious verandahs overlooking the extensive hospital grounds, about thirty acres in extent, and containing flower beds, ornamental shrubs, and trees. The maternity ward unit is arranged as two sections two stories high, each section containing wards with a smaller number of beds and all the necessary rooms and equipment. The children's ward consists of a left and a right wing, each with eighteen cots, the central portion accommodating a kitchen and other sanitary annexes. One wing is divided into sections by glass partitions. The nurses' home is separate from the main building, and has accommodation for 120 nurses; it overlooks the Davyhulme golf course. There are three fully equipped operating theatres situated on the northern side of the main corridor, each being opposite its appropriate ward. The pathology section and the dispensary are on the ground floor, off the main corridor. The x-ray and electro-medical department is most compact and of the most recent type. The isolation block, situated on the eastern side of the main building, is detached, and has accommodation for twelve patients. All the structure stands on a huge reinforced concrete raft. The expense of building the hospital was considerably less than average, the cost of the whole establishment and its equipment being roughly at the rate of £650 per bed.

Manchester Babies' Hospital.

An interesting analysis of the admissions of patients to the Manchester Babies' Hospital, their ages, duration of stay in hospital, condition on discharge, or cause of death, appears in the fifteenth annual report of this institution for the year ending March 31st, 1929. Admissions were fewer than in 1927—381 as against 430—a decline which is explained by the fact that the introduction of measles into the hospital necessitated the closure of certain wards; others had to be closed pending the carrying out in them of redecoration and structural alterations. The demand for the treatment of patients over 1 year old, particularly those suffering from rickets, bronchopneumonia, enlarged glands, asthenia, and general debility, is constantly increasing. A further increase is in the number of premature children treated during each year, the figure for each year from 1924 to 1928 inclusive being, 5, 16, 18, 23, and 37; of those admitted in 1928 twelve died, six within forty-eight hours of admission. The medical officers emphasize the importance of moving these infants only with proper transport, and, whenever possible, of delaying their removal until they are a few days old. During the period under review 34 children were discharged *in statu quo*, some on the ground that they were unsuitable for treatment, others owing to infection in the ward; 263 were discharged improved or cured; 19 were transferred to other hospitals; and 54 died. The percentage mortality was 14.59. Most important among the causes of death were prematurity (12), acute dyspepsia (9), chronic dyspepsia (6), and pneumonia (5). It has been decided to immunize all infants whose parents are willing, in order to help public authorities to deal with the danger of diphtheria at school age.

Scotland.

Laboratory of the Scottish Asylums' Pathological Scheme.

INCORPORATED in the annual report for 1928 of the Scottish Asylums' Pathological Scheme is a statement by Dr. F. E. Reynolds, superintendent of the laboratory, on the work that has been carried out in his own department. During the spring and summer terms of the year under review Dr. Reynolds gave his usual course of lectures on neuropathology at the University of Edinburgh, being associated with Dr. David Orr, who lectured on the anatomy of the central nervous system, and Dr. Slater, who dealt with various general pathological subjects and diseases, of which he had made a special study. The combined course attracted and retained an average daily attendance of about thirty-five students, of whom ten were candidates for the University's diploma of psychiatry. By the sympathetic help and co-operation of the professor of clinical medicine (Professor Edwin Bramwell), an advance has been made towards the realization of Dr. Reynolds's aim to establish a school of neuropathology in Edinburgh. In association with Dr. Logan Turner, Dr. Reynolds has continued his investigations into the paths of infection of the central nervous system, and with Dr. Slater he has studied further cases of grass disease in horses; the results of these and other studies in which he has been engaged are being published in medical journals. The routine work which was undertaken on behalf of various mental hospitals included fifteen bacteriological examinations, 113 examinations for the Wassermann reaction and ten for Widal's reaction, thirty examinations of the cerebrospinal fluid, and nine histological examinations. During the year Dr. Reynolds, on the invitation of the medical superintendents, personally visited a number of mental hospitals, and advised on their pathological work. The laboratory has been promised several financial grants for the ensuing year.

Furunculosis in Salmon.

The Secretary of State for Scotland and the Minister of Agriculture and Fisheries have appointed a committee to investigate the origin, causes, and dissemination of furunculosis and similar infectious diseases among salmon, trout, and other freshwater fish in England and Scotland, and to conduct experiments with a view to ascertaining methods of combating the diseases. The committee includes Professor T. J. Mackie, department of bacteriology, Edinburgh University (chairman); Professor J. A. Arkwright, Dr. T. E. Pryce-Tannatt, and Dr. J. C. Mottram. Since the first outbreak in the south-west of England this disease has chiefly affected salmon and trout, although grayling and, to a less extent, coarse freshwater fish have also fallen victims. During 1928 the disease, which is highly infectious, appeared in several rivers in which it had not been previously observed. The investigation has shown that the physical appearance of fish with furunculosis is by no means constant, less than half of the salmon examined showing the boil-like lesions typical of the disease. The condition of the viscera is also variable, and the only certain means of diagnosis is the isolation of *Bacillus salmonicidus*, the organism of infection. A most important point that has been established is that apparently healthy fish may act as "carriers." There is no danger of infection to mankind through eating affected fish. The work of inquiry is being continued during the present year, and, owing to the uncertainty of diagnosis, it is very desirable that the investigators should have the opportunity of examining all fish which died in suspicious circumstances.

Maternity Service.

In view of the recent discussion at the Representative Meeting on a national maternity service scheme, it is of interest to note that in the agenda for the seventeenth annual conference of the Scottish Association of Insurance Committees, to be held in Ayr on September 27th and 28th, there is a motion by Ross and Cromarty County Insurance Committee to the effect that medical benefit ought to be extended to provide that in all maternity cases there should be: (1) efficient ante-natal examination; (2) sufficient equipment for the prospective mother; (3) efficient nursing, the financial position of the patient being no bar to this being obtainable; (4) adequate medical aid, this being determined, in the majority of cases, in anticipation of actual labour as the result of ante-natal examination; and (5) the keeping of accurate records—ante-natal, natal, and post-natal—in every case in which benefit was received from funds forthcoming under national health insurance regulations.

Benefits of Co-ordination of Nursing Services.

Opening a bazaar, on September 5th, for the benefit of the funds of the Inverness and District Queen's Nursing Association, the Duchess of Atholl emphasized the need for more nurses, especially in the remote parts of the Highlands. A great deal remained to be done in the direction of co-ordination of district nursing associations, and of linking up the town and rural services. In her own county of Perthshire, as a result of a federation system which had been introduced some ten years ago, their nursing work was on quite a new footing of stability and efficiency; they were having the great joy now of being told that all the child welfare work was beginning to show its result in the improved health of the children entering school. In Inverness that same spirit of co-operation between the burgh and rural areas was evident. The Duchess of Richmond and Gordon, who performed the opening ceremony on the second day, spoke warmly on the unselfish nature of the work which the members of the Queen's Nursing Association were doing.

Dunoon Convalescent Homes.

At the annual meeting in Glasgow, on September 2nd, of the Dunoon Convalescent Homes, over which Lord Blythswood presided, it was stated that in the last sixty years 220,000 persons had had the benefit of residence there. During the past year 13,640 weeks' residence had been given to patients, and the average weekly cost per head for food for these, as well as for the staff, was 8s. 6d.; the gross cost for each inmate was 18s. 6d. weekly, and the annual cost for each fully occupied bed was £39 11s. The ordinary income of £12,865 exceeded the ordinary expenditure by about £100, but extraordinary expenditure, entailed mainly in securing a new boiler, had necessitated the withdrawal of £1,000 from the capital fund. Various speakers commented upon the efficiency and economy with which the homes were managed.

Correspondence.

THE PLANTAR RESPONSE IN HYPOGLYCAEMIA.

SIR,—The reports published by Dr. D'Arcy Hart and Dr. Hilda Bond (*British Medical Journal*, May 18th, p. 895) and by Dr. J. L. Newman (ibid., August 24th, p. 345) relative to the character of the plantar responses in insulin coma and in diabetic coma may reasonably claim careful attention, inasmuch as they profess to provide a sharp and confident diagnostic distinction between the one form of coma and the other. The basis for this claim is provided by two statements which are proposed as statements of fact—one that in insulin coma the plantar responses may be extensor, and the other that in diabetic coma an extensor response "apparently never occurs." There follows the inevitable conclusion—obviously of high diagnostic moment—that, given a clinical debate on an individual case between insulin coma on the one hand and diabetic coma on the other, the detection of an extensor response promptly settles the issue in favour of hypoglycaemia, and announces, of course, the appropriate line of treatment. The argument thus stated would be quite beyond challenge had it been possible in the second proposition to write "never" instead of "apparently never." No doubt many cases of diabetic coma, as these come under observation in practice, do not include the presence of an extensor response, but personally I can hardly allow the universal negative, seeing that I have myself described two cases with extensor responses, one being confirmed by post-mortem examination (*British Medical Journal*, September 12th, 1925, p. 477). This experience has its parallel in the coma due to opium poisoning. To judge from many reports and general statements, coma due to opium is not associated with an extensor response; yet there are on record at least three examples to the contrary, and each of these rests on the authority of an independent observer (*Lancet*, February 14th, 1925, p. 360). Hence, without in the least degree undervaluing the contributions made by your correspondents, I suggest that before accepting the diagnostic rule now proposed as an absolute guide we should await the collection of further experiences, and should in the meantime follow the example of careful observation and record set by your correspondents and be exact in noting the condition of the plantar responses—and this, too, at more than one examination—in all cases of coma, whatever be their origin.

So far back as 1911 I presented evidence which seemed to me to justify the proposal that coma *per se* is one of the conditions competent to make possible the extensor response. In recent years many and varied forms of poisoning have been accompanied by this response, and this experience may be held to support my proposal. For while the poisons concerned differ widely in their chemical and pharmacological relations, they have one property in common—namely, the ability to produce coma; it would be difficult to find any other quality common to every member of the group. That coma depending on hypoglycaemia produced by insulin may be accompanied by an extensor response may therefore be presented as in strict accord with the nature of things, and the observation that the response may vary in different phases of the individual case is equally free from the element of surprise. Both of these possibilities are realized in other poisonings, and such experiences all have the further interest that they multiply the occasions which show that toxic influences, as well as convulsive seizures and structural changes, are capable of establishing in the nervous system the conditions that render possible the extensor response. Even if the rule suggested by your correspondents cannot be accepted as absolute, further recorded experiences may perhaps show

such a numerical preponderance of the extensor response *in insulin coma as to make the observation of* helpful importance. And with something short of completeness we need not be acutely disappointed, for Nature, as exhibited in the field of clinical medicine, does not often provide the sharply defined and unyielding line of separation necessary for the ready and rapid sorting of cases into mutually exclusive *pigeon-holes*.—I am, etc.,

C. O. HAWTHORNE.

London, W.1, Sept. 7th.

SIR,—In his note on the subject in the *British Medical Journal* of August 24th (p. 345), Dr. J. L. Newman suggests that the occurrence of the extensor type of plantar reflex during an attack of hypoglycaemia "may come to be regarded as a useful clinical sign in the diagnosis of this condition."

The question arises, Is there any evidence that a plantar reflex of extensor type is more frequently present during hypoglycaemic coma than during coma due to various toxic causes—for instance, hyoscine, veronal, uraemia? It even seems probable that in some individuals (adults as well as children) an extensor plantar response may be obtained during very deep normal sleep (cf. C. O. Hawthorne, "On the occurrence of a bilateral extensor response in states of unconsciousness," *Polyclinic*, October, 1914). It has been obtained during a narcoleptic attack (Kinnier Wilson).—I am, etc.,

London, W.1, Aug. 25th. F. PARKES WEBER.

ANTE-NATAL CLINICS.

SIR,—In common with my colleagues here I was much interested in your leading article on ante-natal clinics on August 17th (p. 315), and in your comment on the Ministry of Health's Memorandum 145/M.C.W.

The reasons for the failure of ante-natal work, if indeed it has failed, to effect any reduction in the maternal mortality rate during the ten years that have elapsed since the passing of the Maternity and Child Welfare Act, are not far to seek. Pre-natal supervision is an adjunct to, and not a substitute for, good obstetrics. "Ante-natal care is successful chiefly where those responsible for it are responsible for the rest of the maternity work, natal and post-natal." The tendency to separate the critical period of pregnancy from labour and the puerperium is bound to have undesirable results. These are commonplaces—as are also the repeated appeals for close co-operation between the various units of a maternity service. Let us have co-operation by all means; but let us first have a midwifery service, and let us build on sound, common-sense lines. In the opinion of all interested in obstetrics the key to the situation is the ante-natal period, which, for this very reason, should be controlled by medical men in the active practice of obstetrics. The Ministry's memorandum rightly suggests "that they [the midwives] should be urged to send their cases to a doctor or a clinic for ante-natal examination at least twice during pregnancy." This, in my opinion, is one of the most salutary expressions in the memorandum, in so far as it indicates the vital importance of the doctor in the ante-natal period.

But surely the time has come for some practical policy to be framed whereby the practitioner shall become a recognized active participant in these ante-natal clinic schemes. Surely the difficulties from an administrative point of view are not insuperable. I have personally organized and supervised many ante-natal clinics, and in consequence would be the last to decry their value and usefulness. At the same time I am the first to perceive their unfortunate tendencies and possibilities. Despite the most punctilious care on the part of the medical officer, patients attend without their doctor's knowledge. Midwives gradually tend to send their patients direct to the clinic, and to short-circuit the practitioner who is likely to be called in to assist in the case of intra- and post-partum complications. It is a matter of the utmost difficulty to avoid overlapping and misunderstandings.

Scattered throughout the country there are now a large number of young practitioners keen and competent to participate in a well-organized maternity service (the word is used in its widest sense and does not imply a State service). These men are trained in the science as well as in the art of obstetrics, and it is quite illogical that their services should not be available to the expectant mother. It is equally illogical that the whole-time official should be in charge of such a critical phase of midwifery—or that the specialist should be dissipating his energies in the routine examination of normal cases. I am quite sure that those consultants who are at present in charge of clinics regard themselves purely as original organizers, and will be glad to hand over their routine work into the only proper hands—those of the general practitioner who is likely to be called in to attend at labour or puerperium. We will then be able to retire into our proper place as consultants in the major obstetrical problems.

I think that the letter from my colleague Dr. E. Farquhar Murray, on September 7th (p. 476), explains very clearly the scheme which we have in view for this area, and which we expect to see in operation in two of our districts in the near future. Other areas would do well to consider some similar scheme.—I am, etc.,

H. HARVEY EVERS,
Honorary Assistant Obstetrician, Princess Mary Maternity Hospital, Newcastle-upon-Tyne.

September 8th.

TREATMENT OF PLACENTA PRAEVIA.

SIR,—With reference to my letter published in the *Journal* of August 10th (p. 278), in which I alluded to the fact that I have been using ovarian extract as a routine in my midwifery cases, I should like to inform inquirers that the solution I employ is "ovarian residue without corpus luteum"; this is supplied in 1 c.cm. ampoules, and is injected deeply into the muscles of the gluteal or the pectoral region. I am indebted to Dr. W. R. Addis of Manchester for his suggesting the use of ovarian extract to me, and I employ it in every case to which I am called early in labour.

The average time taken for complete dilatation of the os in my cases is one and a half to two hours, and one injection is almost invariably sufficient. Uterine contractions increase rapidly in force and in frequency without much, if any, increase in actual pain. The perineum dilates easily, and the last stage is comparatively painless. I always, however, give chloroform and complete the delivery with forceps, because in this way I have control of the delivery and can give the perineum time to dilate. Malpresentations, such as the occipito-posterior, can be corrected with the greatest of ease.

The exhibition of pituitrin or ergot is rarely necessary because of the absence of exhaustion and of the sustained action of the ovarian extract on the musculature of the uterus. The shortness of the labour and the strong tonic effect of the extract give the patient a marked feeling of well-being throughout the puerperium. The milk supply is increased, and, for a day or two, the distension may be troublesome until the adjustment of supply and demand takes place. The physiological action, according to Dr. Addis—and I am convinced that he is right—is a direct one on the uterine muscle, producing tonic contractions of the body and relaxation of the lower uterine segment and of the birth canal.

The application of this remedy to cases of placenta praevia is simple, and no harm can possibly accrue. The blood is already charged with ovarian hormone, and the addition of a supercharge intramuscularly is only assisting nature. Even if one has to resort to the usual procedure of hurrying the case to hospital or nursing home thirty miles away, a single injection of ovarian extract will enhance the patient's chances of reaching the journey's end at least alive.

In the issue of the *Journal* dated August 24th (p. 366) there is a reply to my letter from Dr. Bethel Solomons. The answer to his first question is, that as little attention would have been paid to any remarks made by me, and no full report would have appeared, I elected to bide my time and write a considered article to the *Journal*. The report of the proceedings of the Section and my letter appeared in the same issue, and anyone can count the number of times the words "Caesarean section" occur. I am glad to see

Dr. Solomons has qualified his remarks about the diagnosis, and I thank him for the italics.

I may have been fortunate in my use of ovarian residue, but at least I have not put the blind eye to the telescope. If in Dr. Solomons's practice "results have been absent," there must have been something lacking, either in the material he used or in his powers of observation. The painless contractions of the uterus in an induced case would deceive an observant man, as they frequently deceive the woman herself, and it is difficult to persuade her that she is actually in labour. This is probably due to the small amount of chloretone present in each ampoule.

One of my induced cases was a multipara, aged 42, who had had two previous confinements, both of which, she informed me, were very difficult, and her second child was stillborn. She went over her time with the third, and I decided to induce labour. I gave her six injections during the night at intervals of two hours, and left her at 8 a.m. She was then having strong but absolutely painless contractions. I warned her to remain indoors till I returned. "But, doctor," she said, "I promised to go out to tea to-day!" and in spite of my warning she did so. At 5.30 her hatless husband bounded up my steps, and I followed him to his house. The patient told me she had her first indication that she was in labour while she was having tea, and hurried home. She had had six or eight pains before I arrived; when I examined her the head was on the perineum, and all I had to do was to give her a whiff of chloroform and lift the head over the perineum with forceps. The child was of normal size and there was no laceration, though she had had to be stitched, she informed me, after both her other confinements.

Dr. Solomons's last paragraph is quite uncalled for. If he reads my letter again he will see that I have stated my reason for applying forceps when I did. If I had had more faith in, or experience with, my remedy at that time—nearly three years ago—I should have given further injections of ovarian residue and waited. I have had nearly twenty years of experience of midwifery in general practice, and I was trained in a good school. I may say that I have received complimentary letters from doctors in all parts of the country; many have said they have learned nothing to help them from the report of the Section in the *Journal*.—I am, etc.,

D. C. MACDONALD, M.B.

Manchester, Aug. 26th.

CARE OF THE UNMARRIED MOTHER.

SIR,—I missed your issue containing Dr. R. A. Gibbons's plea for the unmarried mother, but was fortunate enough to see the letter on the same subject in your issue of August 24th (p. 367).

It may interest your readers to know that Queen Charlotte's Maternity Hospital was established in 1739 by a few charitable people for the express purpose of succouring unmarried mothers, the neglect of whom, in those days, frequently resulted in attempts at suicide and infanticide. Although the present-day Queen Charlotte's Hospital has enormously outgrown the institution of nearly 200 years ago, it still offers an asylum to unmarried mothers with their first child, and last year 423 such cases were received out of a total number of 2,375 in-patients. Formerly a distinction was made in the wards between the married and the unmarried women, probably due to a prejudice which was inexcusable in view of the original foundation of the charity. I am glad, however, to say that such a distinction is no longer made, and that no one is aware of the status of a patient except those immediately responsible for the reception of the case. Many an unmarried woman has testified to her gratitude for the treatment at Queen Charlotte's Hospital by a letter or an even more concrete token after leaving the institution.

It is, perhaps, a sign of retrogression that the proportion of unmarried women to married women patients has increased in the last two years, although it may be dangerous to deduce this from the bare figures without taking into account circumstances which do not permit themselves to be expressed by statistics.

In view of the plans to build a new Queen Charlotte's Hospital at Hammersmith on a far larger scale, where eventually a total of 358 beds will include accommodation for at least 200 non-paying patients, it will be realized that this very old charity will have additional opportunities for carrying on its sympathetic work for the unmarried mother.—I am, etc.,

DIGBY C. H. D'AVIGDOR,
Assistant Organizer, Queen Charlotte's National Mother-Saving Campaign.

London, N.W.1, Aug. 23th.

THE NEW VACCINATION ORDER.

SIR,—With reference to the above Order, I cordially agree with the letters of Dr. G. Mahomed of Bournemouth and Dr. F. W. Alexander of Teddington in the *British Medical Journal* of September 7th (p. 476). In the days gone by we have had statistics of outbreaks of small-pox showing that four vaccination marks gave the best protection against that disease; and now the new Order says one mark is to be used—surely a very weak-kneed idea. It would be better to abolish vaccination altogether than to play with efficiency.

I consider cross-hatching with a needle must cause a large amount of trauma and a clumsy way of introducing the vaccine. I started as a public vaccinator in the days of arm-to-arm vaccination, and saw the great benefit when the Government lymph was standardized and sterilization came to the front. I would suggest that the blade of the lancet, not the point, should be the only method used, tightening the skin of the arm with thumb and finger, dropping the edge of the lancet lightly on the skin so as to produce four little red lines without drawing blood, and applying the vaccine before releasing the stretched skin.

As to vaccination producing encephalitis lethargica, why does it not produce it in the infant? Surely this is only another instance of an irritant stirring up a latent disease, as, for example, in the case of eczema, which occasionally follows vaccination in a patient who is the offspring of gouty parents.

Vaccination is an art, and needs care and attention to details.—I am, etc.,

A. Z. C. CRESSY,
Public Vaccinator.

Wallington, Surrey, Sept. 9th.

RACIAL INCIDENCE IN DISEASE.

SIR,—A remark ascribed to Dr. T. A. Goodfellow, speaking on tonsils and adenoids at the Annual Meeting of the British Medical Association, is that there is a greater frequency of adenoids among Jewish children (see *Journal*, August 17th, p. 302).

It is rather surprising how widespread the tendency is to ascribe all sorts of immunities and predispositions to Jews. This is all the more remarkable since most of such statements are quite incapable of proof, for, barring Holland, vital and mortality statistics are not available for the Jews of Western Europe nor for those of the United States. All statements of such a character are therefore based on clinical impressions, but, unfortunately, clinical impressions are not necessarily satisfactory evidence for such wide-reaching generalization.

On the matter raised by Dr. Goodfellow, my personal experience differs from his. I see large numbers of East End children with tonsils and adenoids, including many Jewish children at the London Jewish Hospital, and non-Jewish children at such large centres as the Plaistow Children's Hospital, and at Guy's Hospital; from my experience, I should not have thought there was any greater frequency of this affection in Jewish children. Granting even that more Jewish children with tonsil and adenoids are brought for treatment it does not follow that the condition is in reality more frequent among them: the generally recognized greater maternal care among Jews may very well account for any apparent greater incidence that Dr. Goodfellow may have observed.

The object of this letter is to draw attention to the fact that all the available evidence seems to point to there being very little of a racial basis for any disease. Many diseases have at one time or another been described as being specially common or specially rare among Jews. In a recent symposium Sir Humphry Rolleston and others

discussed the subject of some diseases of the Jewish race (see *Journal*, July 13th, p. 51), and it would appear that the more "Jewish diseases" are investigated, the less "Jewishness" there is left in them. The Jews, constituting a fairly pure race spread over widely different backgrounds, form excellent material for the study of the respective importance of the racial and the environmental factors in diseases, but this is all the more reason for taking very great care to substantiate any impressions as to the prevalence of particular conditions among them.—I am, etc.,

London, W.1, Aug. 22nd. M. SOURASKY.

THE TREATMENT OF RHEUMATISM BY BATHS.

SIR,—In the interesting articles on the above subject which appeared in the *British Medical Journal* of August 24th there are statements which call for comment. On page 352 it is stated that "Dr. Fortescue Fox advances his belief that what he describes as the bath complex (heat and moisture and movement) will be found to be the 'master treatment' of rheumatism"; and, on page 358, that Dr. Fox "expresses his conviction that stimulation of the skin by heat, moisture, and movement in baths is by far the most effectual form of physical treatment in the protean forms of this disease." On a recent visit to the headquarters in Amsterdam of the International League against Rheumatism, Dr. Van Breemen showed us the apparatus employed there in the physical treatment of rheumatism. Of this, 52 per cent. consisted of radiant heat apparatus (34 appliances); 21 per cent. of ultra-violet ray apparatus (14 lamps); 6 per cent. of hydro-electric baths; 4.5 per cent. of diathermy apparatus; 3 per cent. of Scotch douches; and 3 per cent. of vapour baths.

Attention has been drawn to the action of water baths in improving the circulation of the skin and in raising its temperature, which is often habitually lowered in rheumatic disorders. Correctly administered ultra-violet treatment will, however, produce this effect more efficiently and for much more prolonged periods, and it is easy also to induce an intense local hyperaemia in the affected joints or other tissues.

On page 348 occurs a reference to "the advent to London of a central clinic for rheumatic diseases, modelled on the lines of the best Continental ones," and on page 358, "Such an institution does not exist in England, nor has it any Continental prototype." Anyone who has visited the large number of very efficient *Krankenkassen* institutes in Germany realizes that this last statement is hardly correct.—I am, etc.,

London, W.1, Aug. 25th. W. KERR RUSSELL.

MATERNAL MORTALITY.

SIR,—According to Dr. Parlane Kinloch (August 24th, p. 340), normal midwifery is to be taken out of the doctor's hands.

Apparently dirt, overcrowding, poverty, and bad health do not favour puerperal sepsis, and the use of forceps makes no difference, but what apparently does lead to sepsis is a modern maternity hospital and a trained staff. So the old teaching was wrong, and auto-infection was made the scapegoat, while the matter was taken, as they would say in Aberdeen, "to avizandum."

At last the culprit has been found. It is the general practitioner; not because he does not wash his hands, and not because he does not use lysol, or uses forceps, but because he is a "carrier" of the *Streptococcus haemolyticus*. The remedy, then, is to supplant general practitioners by midwives; but we are not told who will supplant the midwives when they too, in due course, become "carriers"! This suggestion reminds one of the remark in *Punch* that there is one law for the rich and one for the poor, but three thousand for the rest of us, whose liberties are already gone.

Because 234 women out of five million people in Scotland die in one year from puerperal sepsis, a whole population is to be browbeaten and a profession turned upside down. No one would welcome the new suggestion more than the average doctor, who suffers more anxiety and later and longer hours for less money in midwifery than in any other branch of his work; but the public would not have it.

It is said, however, that the anxiety is not a numerical one, but is on account of the belief that puerperal deaths are avoidable. It is likely that they are so, in the sense that deaths from accident, tuberculosis, and so forth are avoidable, *and in the sense that pregnancies are*; but it is also likely that, like births out of wedlock, these deaths will occur so long as there persist the innumerable environmental influences making for ill health, and the personal actions making for ill conduct.

How can *Streptococcus haemolyticus* or any other germ be the sole cause of disease? And what is a carrier? He appears to be one in whom a bacteriologist has had the bad luck to find a germ which ought in all decency to have caused a disease, but which did not do so. And what of the new system? A woman does not call in a doctor for her confinement in order to prevent sepsis; she calls him in to be ready for emergencies and to alleviate pain. It is high time something was done to educate doctors on this latter point, but however feeble their efforts may be at present in this direction they would immediately cease under the ministrations of midwives.

If ordinary practitioners are "carriers," why not collect a body of public obstetricians—qualified practitioners who would do nothing else? The profits obtained from this service could then be used to develop a national system of post-graduate study (including payment of locumtenents during a course). Only in this way could we prevent general practice from being the last resort of the specialist, the semi-retired, and the lazy.—I am, etc.,

Argyll, Aug. 25th. TOM ROBERTSON.

SALT DEPLETION BY SWEATING.

SIR,—The discoveries of Dr. Haldane and his collaborators about the efficacy of salt in preventing the ill effects of excessive sweating, to which attention is called in the *British Medical Journal* of September 7th (p. 469), are very useful outside industrial conditions. Many of us are familiar with the tired, stale feeling which is present the day after any unusual exercise in the summer—a long walk, a good deal of tennis, etc. Since hearing of Dr. Haldane's work I have tried the effect of salt in these circumstances, and I feel sure, after my experience last year and this, that it is effective in preventing these unpleasant symptoms. Ordinarily I have added two or three saltspoonfuls of salt to my evening meal. If one is very tired it is, of course, best not to eat anything till next day; in that case it is most convenient to put a good spoonful of salt in the mouth and wash it down with plenty of water. I hope others will try the method; they will, I think, find themselves much more lively next day.—I am, etc.,

London, W.C.1, Sept. 6th. A. E. BOYCOTT.

THYROID AND MANGANESE TREATMENT.

SIR,—With reference to the letters of Dr. Laugwill on July 6th (p. 33), and of Dr. Leslie Fraser on August 24th (p. 369), regarding the results of this treatment, the following extracts may be of interest. They serve to show the biochemical basis of this form of therapy, which was in the first place introduced empirically.

The first extract is from the *Acta Pathologica et Microbiologica Scandinavica*, vol. i, fasc. 4, March 17th, 1925, and is from the report of L. E. Walbum on the therapeutic experiments with metal salts. He found that small manganese injections increased the capacity of the organism to neutralize the various endotoxins with which he experimented—namely, those of the tubercle bacillus, the pneumococcus, the streptococcus, and the staphylococcus—and raised the power of the body to form antibodies.

G. M. Findlay, in the *British Journal of Experimental Pathology*, 1924, vol. 92, and Hurst, in the *Journal of Pathology and Bacteriology*, 1928, xxxi, 306, found that fair doses of manganese gave rise to hepatic cirrhosis in rabbits, guinea-pigs, and rats, with necrosis at the periphery of the lobules. This cirrhosing effect was enhanced by the repeated intravenous injection of living *B. coli*.

The authors performed control experiments with chloroform and phenyl-hydrazine, which caused a central degeneration and very little cirrhosis.

These experiments go to prove that manganese in small doses is stored in the liver and helps in some way in the formation of antitoxin. Walbum found that in larger doses manganese stimulated the growth of bacteria in the body rather than exercising its beneficial effect in increasing the body's resistance. The question of dosage is, therefore, very important; it is clear that if good results are to be obtained it is necessary to follow exactly the technique of this treatment, in which the correct dosage, etc., have been worked out by Dr. Herbert Nott. —I am, etc.,

L. SHILLITO, M.B., B.Ch.Cantab.

West Runton, Norfolk, Aug 27th.

REMUNERATION OF MEDICAL WITNESSES.

SIR,—The recent controversy in the press regarding the fees allowable by courts of law to medical witnesses prompts me to put before you my own recent experience.

At the request of the police I gave evidence before a metropolitan police magistrate on behalf of the prosecution in a criminal charge. The case was of such gravity that the police magistrate remanded the prisoner to the Central Criminal Court. I was detained at the court from 11 a.m. until 1.15 p.m., and gave what was presumably expert evidence, since it was based upon the consideration of facts of a professional nature. For this period of detention, and in remuneration for this special aid in the cause of justice, the fee allowed was 15s. Accompanying the postal order for this amount was a note stating that "no inquiry respecting the amount now sent, which is the amount ordered by the magistrate sitting at the court where the case was heard, can be answered." The amount is, apparently, "governed by a scale approved by the Secretary of State."

I venture to suggest, having regard to the amount of training required to make the expert, and the undoubted value of his evidence in legal proceedings, that the fee is utterly inadequate, and that, considered in relation to the apparent cost of legal expert evidence, the fee under consideration becomes a subject of jest.—I am, etc.,

ERICHSEN S. PAGE, M.B., B.Ch.Cantab.,
London, W.9, Aug. 24th. F.R.C.S.Eng.

The Services.

DEATHS IN THE SERVICES.

Lieut.-Colonel Winfred Kelsey Beaman, D.S.O., R.A.M.C. (ret.), died at Durban, Natal, on May 9th, aged 46. He was born on November 7th, 1882, and was educated at Charing Cross Hospital, where he gained the Huxley scholarship in 1901, and the Governors' gold medal for clinical work in 1906. He took the M.R.C.S. and L.R.C.P.Lond. in 1906, and, after his retirement from the service, the M.R.C.P.Lond. in 1923. After filling the posts of house-surgeon at Charing Cross Hospital and resident medical officer of the Kent County Sanatorium at Lenham, he entered the R.A.M.C. as lieutenant on January 29th, 1907, gaining the Parkes memorial medal at the R.A.M.C. College. He became major after twelve years' service, went on half-pay on October 9th, 1922, and retired with an honorary step of rank in the following year. After his retirement he filled the positions of honorary physician to the Ministry of Pensions Mount Pleasant Hospital, Chepstow, honorary physician to the Pontypool and District Hospital, and honorary consulting physician to the Chepstow and District Hospital and to the Victoria Cottage Hospital, Abergavenny. He served throughout the recent great war, when he was twice mentioned in dispatches—in the *London Gazette* of January 1st, 1916, and January 4th, 1917—and gained the D.S.O.

Captain Henry Anthony de Lom, R.A.M.C. (ret.), died in London on April 12th, aged 73. He was born on June 6th, 1855, at Stratford, Essex, educated at *Toronto* and at St. Thomas's, and took the M.R.C.S. and *L.R.C.P.London in 1881*. He entered the army as surgeon on August 4th, 1883, was placed on half-pay, on account of ill health, on September 28th, 1894, and retired five years later. He served in the Sudan in the Nile expedition of 1885, receiving the Egyptian medal with a clasp and the Khedive's bronze star.

Obituary.

SIR SEYMOUR JOHN SHARKEY, M.D., F.R.C.P.,

Consulting Physician to St. Thomas's Hospital.

WITH deep regret we have to record the death, on September 6th, after a short illness, of Sir Seymour Sharkey, at the age of 82.

Seymour John Sharkey was born at St. Peter's, Jersey, on July 10th, 1847, being the third son of Edmund Patrick Sharkey, M.D., of Trinity College, Dublin, who practised at Ballinasloe, Ireland. He was educated at Christ's Hospital, and in 1865 entered Jesus College, Oxford, with an open classical scholarship. After taking a second class in classical moderations, he won a first class in the natural science finals, and in 1873 was awarded the Radcliffe Travelling Fellowship. In accordance with the conditions of the fellowship he spent the greater part of the next three years in scientific work at Berlin, Paris, and Vienna. Before closing this summary of Sharkey's Oxford career it may be of interest to refer to an incident which also found mention in an obituary notice of Sir Ray Lankester published in *Nature* on August 24th. Sharkey and Lankester were the two winning candidates for a fellowship at Oxford, Huxley being the examiner. Twice Huxley sent back the papers of these two candidates, saying that it was impossible to choose between them, and when the choice was finally made in favour of Lankester it was on the ground that the subject he had taken was the better suited for the purpose.

As soon as he was free to do so, Sharkey entered the medical school of St. Thomas's Hospital, in the service of which he was to spend the greater part of his life. He graduated M.B.Oxon. in 1875, and four years later obtained the diploma M.R.C.P. In 1885 he became F.R.C.P., and proceeded M.D. in 1888. Having held various resident posts he was appointed assistant physician in November, 1879, became full physician in November, 1890, and consulting physician on his retirement in June, 1910.

Sharkey very quickly made a great reputation as a teacher, first in the out-patient room and then in the wards. Murchison, who was acknowledged to be one of the greatest teachers of the day, was still in charge of beds, and it was always said that he was the model upon whom Sharkey based his method. At all events Sharkey had a remarkable power of attracting men of every grade of intellect. His visits to the wards were always attended by a large crowd of students, who discovered the round to be not only highly instructive but a very good afternoon's entertainment at each other's expense, the fun being that nobody knew who would be the next victim of the teacher's mordant wit. Sharkey's style of teaching by the Socratic method was certainly of a very challenging kind, and unless one was prepared for hard knocks it was better to stay away. But all this was only by-play. Through it all ran a continuous stream of the very best clinical teaching, based on constant and accurate observation of the patient. A clinical clerk was once given a case for examination and diagnosis. He reported to Sharkey that it was mitral stenosis. "Well, Mr. Martin," said Sharkey in his best hectoring way, "tell me why I don't believe that it is a case of mitral stenosis." "No doubt because I say it is," replied the clerk, and both he and the teacher joined in the general laugh. Sharkey never forgot a portly house-physician of his who said that his six months' office had cost him two stone in weight.

During Sharkey's early days at St. Thomas's the late Professor Osler was settled in London, and for several months constantly accompanied him on his visits to the wards. Years afterwards Osler was distributing the prizes in the medical school, with Sharkey sitting on the platform near him. In the course of his speech Osler leaned over and put his hand on Sharkey's shoulder, saying, "This is the man who taught me all the medicine I know." It was a graceful gesture worthy of both.

As a physician Sharkey was also in the first class, a position largely due to the fact that he practised the habit of intensive observation, which he was never tired of inculcating into his pupils. Moreover, he made constant use

of the best auxiliaries to medicine which were available at that time. For many years he conducted post-mortem examinations on two days of each week, and those were the days when all pathology was included in the post-mortem room and the microscope. Surgery was just then coming into its own, and in his surgical colleague and lifelong friend H. H. Clutton he had a co-operator worthy of him. Those two men represented for the St. Thomas's world of that date the advancing edge of scientific medicine and surgery.

Sharkey was interested in every branch of medicine, but more particularly in that which included the functional disorders of the nervous system. He was one of the first men in this country to adopt the Weir Mitchell form of treatment, and did so with great success. At the Royal College of Physicians Sharkey delivered the Goulstonian Lectures in 1886 and the Bradshaw Lecture in 1906. He was also examiner from 1893 to 1897, councillor from 1902 to 1904, and censor from 1908 to 1912.

In private practice Sharkey did not attain to the measure of success that he deserved. The fact that he was constantly called in by his colleagues to advise as to themselves, their wives, and families shows that any deficiency in a more remunerative form of practice was not due to any failure to arouse confidence. And yet his old pupils were both numerous and prosperous. They were still devoted to their old teacher, and used to speak of him in terms of warmest affection. On the occasion of his retirement from the active staff in 1910 they organized a dinner in his honour; it was attended by over one hundred, and was a brilliant success. And yet they did not call him in to see their patients, at all events not on a scale commensurate with his abilities or their debt to him. The explanation which is accepted by those who should know is that they were afraid that Sharkey would treat them with the scant respect which was stimulating, and even enjoyable, when practised in the ward with other students as their fellow victims, but would be very disquieting in the presence of adoring private patients.

Even St. Thomas's days had to come to an end, and in 1910 Sharkey, though still in the prime of health and vigour, had to retire from the active staff and became consulting physician. Fortunately, about two years later he was appointed medical referee to the Treasury, and this gave ample scope for his best energies. In this capacity he stood as final arbiter in any dispute involving medical questions between the Government and its employees. Not very long after his appointment the war broke out, and, as it continued, the call for the referee's services was increased manyfold. Sharkey rose to the emergency, as anyone who knew his ability and courage could have foretold. At one time the question was raised on the part of the trade unions concerned whether they should not claim to have a representative as well as the Government; but such was the impression produced by Sharkey's spirit of justice that the matter was dropped, and the Treasury medical referee from that time has continued to represent both the Government as employer and the workman as employee. This post was held by Sharkey till July, 1923, and then had to be vacated with regret on both sides on account of technical limitations of age. This marked the end of his professional career.

Throughout his life Sharkey was devoted to open-air sports, and had a natural facility for them. Dry-fly fishing was his chief recreation for the greater part, and for many years his spare time was spent in company with his old friend Sir George Savage at his cottage on the Test. Golf was added in the course of time. He had no special interest either in music or the pictorial arts, but he was a keen lover of beauty. Friends and grateful patients were aware of this, and his room was always full of the flowers they had sent him. Fortunately he enjoyed magnificent health, and he has been heard to boast of not knowing what it was to feel tired. He gave the impression of exuberant vitality, and was a most exhilarating companion. Only during the last year or two did he show signs of advancing age, and when the final breakdown came it was mercifully short.

No apology is offered for what may be put down to St. Thomas's egotism in this sketch, for it could not be otherwise. It only expresses the fact that Sharkey gave his whole life to the place. He was attached to no other hospital, and to this one he gave his all—and that was good indeed. His devotion had its reward in the universal affection with which he was regarded by colleagues and pupils alike.

H. G. T.

A memorial service was held in the chapel of St. Thomas's Hospital on Monday, September 9th, at noon; it was attended by a large company, which included representatives of the Royal College of Physicians, of the Treasury, and of St. Thomas's Hospital. The Rev. J. Anderson Davies, Assistant Hospitaller, officiated. The funeral took place at Kensal Green on the same day and at the same hour.

SIR JOHN CAMPBELL, M.D., M.CH., F.R.C.S.,

Senior Surgeon to the Samaritan Hospital for Women, Belfast, and *Consulting Surgeon to the Belfast* Maternity Hospital.

SIR JOHN CAMPBELL, whose death at his residence at Craigavad, County Down, on August 31st, we announced last week, was one of the most famous and distinguished surgeons in Ireland. He had been in failing health for some time, after leading a very active life in which he never spared himself, resembling in this respect his brother, Robert Campbell, surgeon to the Royal Victoria Hospital, Belfast, who died in 1920.

John Campbell was born in 1860, at Templepatrick, County Antrim; his ancestors came originally from Ayrshire, but had been associated with Ulster since the "Plantation" in the time of James I. He received his early education at the Royal Belfast Academical Institution, from which he passed to Queen's College, Belfast, and graduated B.A. in 1883, winning the senior scholarship in natural history. In the following year he proceeded M.A., with first-class honours, in the then new Royal University of Ireland; three years later he graduated M.D., M.Ch., M.A.O. He continued his medical studies in the London Hospital, and in the Rotunda Hospital, Dublin, and afterwards visited Paris, Vienna, Munich, Heidelberg, and Bonn. He obtained the diploma M.R.C.S. in 1888, and the F.R.C.S., by examination, in 1891. He acted for some time as locumtenent for the professor of natural history in Belfast, and was a demonstrator in anatomy in the medical school under the late Professor Redfern in 1888. He was appointed assistant surgeon to the Belfast Hospital for Sick Children in 1891; at the close of the following year he was elected surgeon to the Samaritan Hospital for Women, and, later, assistant in the Belfast Maternity Hospital. From this time he devoted himself entirely to the obstetrical and gynaecological branches of medicine, becoming widely known and respected for his clinical ability, his skill in organization, and his breadth of vision. He contributed many articles to medical journals, and wrote a book entitled *Obstetrics and Gynaecology: A Textbook of Treatment*, which was originally intended to form one of a series of three. His brother, the late Mr. Robert Campbell, was commissioned to write the volume relating to surgical treatment, and Dr. W. Calwell that on medical treatment.

In stimulating the progress of Irish university education John Campbell played a prominent part. He was president of the Royal University Graduates Association, and for some time a member of the senate of the University, on the dissolution of which he received the honorary degree of LL.D. Later he was elected chairman of convocation of the Queen's University, Belfast. He was president of the Ulster Medical Society in 1902 and 1903. He rendered great services to the British Medical Association, and was a member of Council from 1899 to 1900; he was one of the honorary secretaries of the Section of Obstetrics and Diseases of Women at the Annual Meeting at Edinburgh in 1898; a vice-president of the Section of Obstetrics and Gynaecology at the Meeting at Oxford in 1904; and president of that Section when the Association met at Belfast in 1909. During the war he was the senior surgeon of the British Red Cross Hospital at Wimereux. He represented the Queen's University in the Parliament of Northern Ireland until the dissolution a few months

ago, when he retired. He received the honour of knighthood in 1925.

We are indebted to Dr. W. CALWELL for the following appreciation:

It would be difficult to estimate the usefulness of such a full and varied career. Sir John Campbell raised gynaecology to a scientific and advanced position in Ulster. His skill and success as an operating surgeon in these branches were fully realized by the community, and for a very long time he was an acknowledged leading consultant. Although in later years he withdrew from full active work, yet both the general public and the medical profession were always eager to have his aid and advice in determining the correct lines of treatment. In 1902 he married Miss E. F. Fitzsimon of Tralee, by whom he had three sons; of these two are living. Deep and widespread sympathy is felt for the family.

We regret to record the death, at the age of 83, of Dr. JAMES ALFRED HARRIS, which took place on September 7th, at his home at Chorley, Lancashire. James Alfred Harris, having received his medical education at Edinburgh, obtained the diploma M.R.C.S.Eng. in 1869; he graduated M.B.Lond. in 1870, and proceeded M.D. in 1874. A year later, having held appointments as house-surgeon to the Northern Hospital, Liverpool, resident medical officer to the Mill Road Hospital, Everton, and resident physician to the Royal Infirmary, Edinburgh, he started private practice in Chorley, where, in the course of a long career, he became consulting medical officer of health for Chorley borough and rural district, honorary consulting surgeon to Rawcliffe Hospital, and a justice of the peace for County Lancaster. He was a member of the British Medical Association. We are indebted to Sir James Barr for the following appreciation: When I was appointed junior house-surgeon to the Northern Hospital, Liverpool, Dr. Harris had been promoted to the senior appointment on the resignation of Dr. David John Hamilton, who had obtained the Astley Cooper prize, and afterwards became professor of pathology in Aberdeen University. Dr. Harris, who was about four years my senior in the profession, and I at once became warm friends, and now an unbroken friendship of slightly over fifty-five years has been severed. Although Harris studied in Edinburgh, he graduated at the London University, the degrees of which were then not very numerous. He was justly proud of his London degrees, but sometimes I thought that they handicapped him, in much the same way as they have affected others, in making him rest satisfied with past achievements. However, as it turned out, they were much to his advantage in his future career, for he had no bent for research work, and in private practice they at once gave him a status which otherwise he might not have so rapidly attained. In 1875 Dr. Harris had an opportunity of succeeding to a large practice at Chorley, owing to the serious illness of the incumbent. I then thought that he was sacrificing future prospects for present advantages. However, it turned out otherwise. He was an earnest student, knew his work well, and kept himself well abreast of modern advances in medicine. His genial manner and high standard of professional probity endeared him to his patients and professional brethren. He took much interest in public health matters, and was part-time medical officer of health for nearly fifty years to Chorley borough and Chorley rural district. Although he was not a contributor to medical journals, his reports as medical officer of health were models of perspicacity. The last time I saw Dr. Harris was in the early twenties, when I was taking part in a war memorial ceremony at Chorley. My wife and I had lunch with him and Mrs. Harris. He was then preoccupied with his favourite subjects of Hebrew, Greek, and Latin. He continued at work till 1924, when he had a very serious illness, after which he retired from practice and from his medical appointments. He always took a keen interest in the British Medical Association, though he never held any very important appointments, and he kept clear of the turmoil in Lancashire over the Midwives Act and the National Health Insurance Act. He will long be remembered by those who knew him as a genial, upright, and intellectual member of the medical profession. He had a very happy married life, and leaves a widow, but no family.

The death occurred at his residence in Edinburgh, on August 30th, at the age of 70, of the Rev. WILLIAM MENZIES ALEXANDER, M.D., professor of apologetics and pastoral theology in the Free Church College, Edinburgh. Dr. Alexander was educated in Glasgow, and, after graduating B.Sc. in 1885, was appointed professor of biology and chemistry in the Wilson College, Bombay. In 1888 he graduated M.B., C.M.Glasgow, and was appointed assistant to Professor Napier. He obtained the degree of B.D. and was ordained in 1889, and proceeded M.D. in 1891. He went back to Bombay for a period, was repeatedly examiner to the Technical College and the University there, and was elected a Fellow of the University in 1894. His hearing having become impaired through illness, he returned from India, and was successively lecturer in the Free Church College, Glasgow, and in the United Free College, Aberdeen. Dr. Alexander was elected professor in the reconstituted Free Church College in 1904, and the highest honour of the Church—the moderatorship of the general assembly—was conferred on him in 1911. He obtained the degree of D.Sc. in 1919, and the honorary degree of D.D. was conferred upon him in 1927 by the University of Edinburgh. In addition to his educational work, which was very highly valued, Dr. Alexander was the author of numerous books and papers on scientific, social, medical, religious, and theological subjects. His deafness, although latterly great, was borne with commendable patience, and he cultivated to the last his powers of assimilation, the most recent events of public life being invariably turned to illustrative use in his lectures. During the last assembly Dr. Alexander was presented by the ministers of the Church, most of whom had been his students, with an address of congratulation on the completion of twenty-five years' service as professor in the Free Church College.

Dr. WALTER ERICHSEN POWELL, who died after an operation, at the early age of 34, on August 31st, received his medical education at Charing Cross Hospital, where he obtained the diplomas M.R.C.S., L.R.C.P. in 1917. He was then appointed temporary surgeon in the Royal Navy, and served in the "Q" boats, chiefly in the Mediterranean, up to the end of the war, when he joined his father in practice in Brighton, and became anaesthetist at the Brighton Infirmary and at the Dental Hospital, and deputy anaesthetist at the Throat and Ear Hospital. He was the joint author of an article in the *Journal of Anatomy and Physiology*, entitled "A case of manifestation of occipital vertebra, and fusion of the atlas with the occipital bone." Dr. Powell was a popular member of the British Medical Association, and also of the Brighton and Sussex Medical and Chirurgical Society. His funeral on September 3rd was attended by every section of the medical profession locally, representatives of hospitals, the British Medical Association, and the public bodies of the town, and a large circle of friends. A colleague writes: Dr. Powell was a most kind and generous doctor, beloved by the poor and by all his colleagues. It was said of him that he was unable to do a dirty trick to anyone, and his hobby seems to have been helping lame dogs over stiles.

The following well-known foreign medical men have recently died: Professor RUDOLF BALINT, professor of internal medicine and director of the first medical clinic at Budapest, aged 55; Dr. CHARLES JEAN JULIAN DÉPERET, dean of the faculty of sciences of Lyons and member of the Institut de France; Dr. WILHELM ELLENBERGER, professor of physiology and anatomy at Dresden; Professor JONAS WAERN, professor of the surgery of children at Stockholm; Dr. FRANÇOIS BENOÎT of Liège, formerly president of the Belgian Society of Ophthalmology; Dr. PAUL SALMON of the Institut Pasteur, Paris; Dr. JOHN PHILLIPS, in the recent disaster at the Cleveland Clinic Hospital, where he was director of medicine, aged 50; and Dr. BENJAMIN KNOX RACHFORD of Cincinnati, author of a work on diseases of children, aged 71.

Medical News.

LORD GORELL, C.B.E., M.C., will preside at the opening of the centenary session at King's College Hospital Medical School, Denmark Hill, S.E., on Wednesday, October 2nd; Sir Gregory Foster, Vice-Chancellor of the University of London, will deliver the introductory address at 2.30 p.m. The annual dinner will be held the same day at 7.30 p.m., at the Connaught Rooms, the chair being taken by Dr. H. Willoughby Eyle, dean of the Medical School.

BY arrangement with Imperial Airways, Ltd., a specially conducted visit to the air port of London will take place on September 21st, at 2.30 p.m., the proceeds being given to King Edward's Hospital Fund for London. The party will assemble at Charing Cross Underground Station, Victoria Embankment, and will be conducted by private omnibus to Croydon. Tickets, price 7s. 6d., can be obtained from the Secretary, King Edward's Hospital Fund for London, 7, Walbrook, E.C.4. For an additional charge of 10s. 6d. visitors will be given an opportunity of taking short flights in small aeroplanes provided by the Surrey Flying Services.

THE seventy-fourth annual exhibition of the Royal Photographic Society of Great Britain will be held from September 14th till October 12th at the premises of the society, 35, Russell Square, W.C.1. The exhibition will be formally opened on the evening of September 13th by the Lord Mayor of London.

THE Fellowship of Medicine announces that there will be a special whole-day post-graduate course for men only in medicine, surgery, and the specialties, at the Westminster Hospital from September 16th to 28th. There are in progress at present an afternoon course in diseases of infants at the Infants Hospital, Vincent Square; a course in psychological medicine on Tuesday and Saturday mornings, at 11 o'clock, at the Bethlem Royal Hospital. A whole-day course in gastro-enterology will be held at the Prince of Wales's Hospital, Tottenham, from September 30th to October 4th. In October there will be courses in ophthalmology, tropical medicine, gynaecology, diseases of children, and diseases of the throat, nose, and ear; a whole-day course in medicine, surgery, and the specialties at the Metropolitan Hospital, Kingsland Road, and an evening M.R.C.P. course. Detailed syllabuses and information about post-graduate work in London may be obtained from the Secretary of the Fellowship, 1, Wimpole Street, W.1.

DURING the sixth annual meeting of the International Society of Medical Hydrology, to be held at Budapest from October 13th to 18th, medical discussions will take place on the 14th and 15th on the action of hypertonic waters and the use of baths and waters in cardio-vascular affections. A meeting of the Ligue Internationale contre le Rheumatisme will be held on the 16th for discussing the relation between acute and chronic rheumatism in the various countries, and the haematology and serology of rheumatism. Excursions will be made to the "Bitter Water" springs, bathing establishments, Lake Balaton, etc. At the conclusion of the meeting the party are invited to view the hospitals and clinics at Vienna and the establishments at Baden. Special reductions in cost are offered to members of the society and their friends. The English party will leave London on Friday, October 11th. A few vacancies are available for medical men or women interested in hydrology. Full particulars will be given on application, as soon as possible, to the Honorary Secretary, International Society of Medical Hydrology, 139, Marylebone Road, London, N.W.1.

ON the occasion of its annual congress, the Chartered Society of Massage and Medical Gymnastics will hold a dinner at the Café Royal on Wednesday, October 16th, at 7.45 p.m.

ON September 5th, at a largely attended meeting held in the English Congregational Church, Caerphilly, Dr. T. W. Thomas was presented by the public of Caerphilly with a portrait of himself to mark its appreciation of his services during forty years of practice in the district. Dr. Thomas has been for many years a keen member of the British Medical Association: he was vice-chairman of the Cardiff Division for the year 1925-26 and chairman for the two years 1926-28. He was also a member of the general executive when the Association met in Cardiff in 1928.

A CONGRESS of the International League against Rheumatism will be held at Budapest from October 13th to 19th, and in Vienna from October 19th to 20th. The following subjects will be discussed: the medical and social significance of chronic and acute articular rheumatism in different countries, and the importance of examination of the serum and blood in rheumatic diseases.

A POST-GRADUATE course of lectures and demonstrations in practical paediatrics, including instruction in the examination of children, clinical pathology, and radiology, will be held from November 4th to 16th at the Clinique Médicale Infantile of the University of Lyons. The fee for the course will be 200 francs, and further particulars may be obtained from the Secretariat de la Faculté de Médecine, 18, Quai Claude-Bernard, Lyon, to whom application must be made not later than October 25th.

A POST-GRADUATE course in cutaneous and venereal diseases will be held at the Madrid faculty of medicine, under the direction of Professor J. S. Conisa, in November. Further information can be obtained from Dr. Gay, Españoleto 22, Madrid.

THE British Social Hygiene Council has issued in pamphlet form a statement of the services it is able to place at the disposal of local authorities in furtherance of their schemes for combating venereal disease. The council estimates that to maintain its present machinery for supplying literature, films, public exhibitions, lectures, van campaigns, and expert assistance in the organization of health and social hygiene weeks, it will require at least £10,000 per annum, and points out that unless the local authorities continue to pay from their block grants an amount equivalent to that hitherto paid direct to the council by the Minister of Health, it will find it impossible any longer to render these services.

THE Vocal Therapy Society was founded in 1918 to promote the physical and mental health of invalid ex-service men, through speech, song, and efficient breathing, and to form hospital and other ex-service singers into choirs called the "King's Services Choirs." Five choirs are now at work, and the society in its report for the year 1928 states that during the year three concerts were given—two at the Chelsea Polytechnic Institute and one at the Star and Garter Home at Richmond. *It is to the society's credit that through its* efforts many men invalided in the war—shell-shock cases with speech defects and even aphonia—have been completely cured; and, though some of them may retain slight hesitation in speech, they are now able to talk to their fellow men and work at their old trades. The secretary is Miss K. S. Malden, 27, Grosvenor Place, S.W.1.

Letters, Notes, and Answers.

All communications in regard to editorial business should be addressed to ***The EDITOR, British Medical Journal, British Medical Association House, Tavistock Square, W.C.1.***

ORIGINAL ARTICLES and LETTERS forwarded for publication are understood to be offered to the *British Medical Journal* alone unless the contrary be stated. Correspondents who wish notice to be taken of their communications should authenticate them with their names, not necessarily for publication.

Authors desiring REPRINTS of their articles published in the *British Medical Journal* must communicate with the Financial Secretary and Business Manager, British Medical Association House, Tavistock Square, W.C.1, on receipt of proofs.

All communications with reference to ADVERTISEMENTS, as well as orders for copies of the *Journal*, should be addressed to the Financial Secretary and Business Manager.

The ***TELEPHONE NUMBERS*** of the British Medical Association and the *British Medical Journal* are *MUSEUM 9861, 9862, 9863,* and *9864* (internal exchange, four lines).

The ***TELEGRAPHIC ADDRESSES*** are:
EDITOR of the *British Medical Journal*, *Aitiology Westcent, London.*
FINANCIAL SECRETARY AND BUSINESS MANAGER (*Advertisements, etc.*), *Articulate Westcent, London.*
MEDICAL SECRETARY, *Medisecra Westcent, London.*

The address of the Irish Office of the British Medical Association is 16, South Frederick Street, Dublin (telegrams: *Bacillus, Dublin*; telephone: 62550 Dublin), and of the Scottish Office, 7, Drumsheugh Gardens, Edinburgh (telegrams: *Associate, Edinburgh*; telephone 24361 Edinburgh).

QUERIES AND ANSWERS.

DR. GRIFFITH EVANS (Caernarvon) writes: Can any reader please refer me to the memoir written by one of the leaders of the profession in the last generation wherein he stated that the one great mistake of his life was not to recognize syphilis when he saw it?

BOYS' SCHOOLS IN SWITZERLAND.

DR. F. DAVIDSON (Hull) asks for help in finding a boarding school in a high altitude in Switzerland for a boy, aged 13, who is suffering from asthma, caused by a slight fibrosis of the lung after bronchitis. The condition is definitely not tuberculous, and it is thought that the patient requires a higher altitude than the tuberculous stations.

TREATMENT OF MENORRHAGIA.

"PERSISTING" would be grateful for advice in the following case: A young [illegible] healthy, came under treatment for [illegible] which had prevented any [illegible] etc. A curettement, followed by a course [illegible] effected a temporary cure. Three [illegible] recurred, and has become persistent.

tried: calcium lactate, a preparation of placenta and mammary glands, ergot, sistomensin, ergotinin, styptol, lodal chloride, infundin, haemoplastin. Some of these have effected a slight improvement; recently she has relapsed. Operative intervention is not welcomed.

STERILE MILK INJECTIONS.

DR. J. THOMPSON (Devizes) writes: In reply to Dr. Donald's inquiry on September 7th (p. 481) about sterile milk injections for chronic suppurative otitis media, I may say that, in my experience, the method is of distinct value in acute cases, but when the infection has become really chronic it does not seem to achieve the desired result. For early cases, however, and by early cases I mean those which have been going on for a month at most, it has been most successful—in fact, one might almost call it a specific method of treatment. The condition of the external auditory canal requires the greatest attention first, and I have the ear syringed every three or four hours with 1 in 5,000 lysol solution, followed by careful drying with sterile wool on wooden probes. This is done for two days, and then 1 inject into the buttock 3 c.cm. sterile milk, brought to the boil twice in a flask. A reactionary temperature occurring then is evidence of a leucocytosis having been established, and the ear becomes dry in about two days. After the injection has been given, the syringing is stopped, and only dry mopping with dressed sterile probes is necessary. For the more chronic cases zinc ionization, after careful and complete cleansing of the canal, has given me a certain number of cures, but everything depends on the size of the perforation being large enough to ensure the zinc solution actually reaching the middle ear, and also the whole of the infected mucous membrane.

INCOME TAX.

Erection of New Professional Buildings.

"A. M.'s" surgery and consulting rooms were part of his dwelling house; he is providing new accommodation by building at the back of his house, with a garage in substitution for a dilapidated wooden one. Can he claim any allowance for this expenditure?

*** No; it represents capital outlay on improvements. If the garage were partially reconstructed some allowance could perhaps be obtained as equivalent to expenditure on repairs.

Proportion of Rent, etc.

"J. H. F." has been allowed one-third of his total expenditure on rent and rates and electricity, and desires advice as to whether he should appeal for a larger allowance.

*** The premises consist of a two-story house and garage. Taking the annual value of the ground floor to be about twice that of the other floor (of which a part is unused), and seeing that about half the ground floor is used for professional purposes, the proportion of one-third would be correct on the basis that it does not cover anything for the garage or servants' accommodation—both these portions of the premises have some reference to professional purposes. On the whole, we consider one-third too little, and that the true proportion lies somewhere between one-third and one-half. With regard to electricity the point is more difficult. In view of the fact that an electric cooker is used, and remembering that private consumption of light extends usually to a later hour than professional consumption, we cannot advise an appeal against the one-third basis.

LETTERS, NOTES, ETC.

HISTORY OF THE I.M.S.

R. SOCRATES NORONHA (Bombay) writes: In your issue of June 29th, at page 1184, there is a description of the annual London dinner of the Indian Medical Service held at the Trocadero Restaurant, with Lieut.-Colonel D. G. Crawford in the chair. In the course of his speech Colonel Crawford is reported to have related, among other historical facts, the following: "And the Indian Medical Service started, one strong! For defence they had a handful of Goanese peons. That small body of merchants and writers had grown into the great Civil Service of India, that half company of Goanese peons had expanded into the Indian army, the finest army in the world." I wish to draw your attention to the fact that the Goanese come from Goa—a Portuguese territory in India—and that both because of their nationality as well as choice of professions they could not have been and are not soldiers of the Indian army, which is mainly composed of Marathas, Rajputs, Punjabis, and Gurkhas.

*** We have referred Dr. Noronha's letter to Colonel Crawford, who makes the following comment:

The early garrisons of Bombay and Calcutta were chiefly composed of *Topazes*, men of mixed Portuguese and Indian descent, the latter the Indian strain, greatly predominating. Fryer in his *Travels* (p. 65) says that the garrison of Bombay in 1673 consisted of 300 Europeans and 400 Topazes; and it is probable that the small defensive force at Surat, half a century earlier, was similarly composed. Though the Indian army at the present time is recruited chiefly from Sikhs, Punjabi Musalmans, Pathans, Dogras, Rajputs, Gurkhas, and Marathas, it is certain that none of the first six races were serving the Company as soldiers in the seventeenth century, though there may have been some Marathas. Long before the English visited India the Portuguese had traded and more or less settled all round the coast. Their descendants, the class who served as Topazes, are still numerous both in Calcutta and Bombay, and in Bengal at least are usually called Goanese, though, no doubt, the majority of them never saw Goa. That city, of course, is the headquarters of what is now the chief, almost the only, possession of Portugal in India, and never belonged to Britain. Bombay, as is well known, was itself once a Portuguese possession, and was given to England as the dowry of Catharine of Braganza, Queen of Charles II, and handed over by the King to the Company.

PHYSIOLOGY AND CLINICAL MEDICINE.

DR. JAMES M. MCQUEEN (Halesowen, Birmingham), in the course of a letter on Professor Fraser's paper "The place of human physiology in the training of medical students" (August 31st, p. 369), writes: Professor Fraser's main thesis is based on the assumption that the physiologists and the clinicians are of necessity confined in separate watertight compartments. Certainly, if memory were the chief faculty of the human brain, the task of mastering the contents of large treatises on physiology and on clinical medicine would be too great for any one individual. The real truth, however, is that the human brain has a supreme capacity of ignoring both kinds of treatises, except when they are required for some specific purpose. The general practitioner who is interested, for example, in the subject of shock, can read in the literature all that the clinicians and the physiologists have to say about it. It is, however, open to him to think that a gap exists in our knowledge of the circulation in the liver during shock and to devise experiments to settle his curiosity. I suggest that as long as he can read a book and get out of it what he wants, and can recognize when his mental curiosity is not satisfied, then he can be both a physiologist and a clinician combined. The present need is not to train a new race of human-physiology tutors to lay more memory burdens on unfortunate undergraduates, but to teach the medical student how to read books and, when he is dissatisfied with current explanations, to make investigations for himself. Let the clinical teacher in the ward follow his curiosity over unanswered questions in physiology in company with his pupils; he will then find that both he and they can quite easily become physiologists, and that the so-called gap ceases to exist. It is the spirit of inquiry that requires to be taught, and that spirit is the same in physiology as in all other sciences.

HERPES ZOSTER AND VARICELLA.

DR. E. HERZBERG (London, N.W.11) writes: A man, aged 63, developed a very severe attack of herpes-zoster trigeminus, and on the fourth day of his illness a rash appeared over the whole of his body. It was an obvious attack of chicken-pox. Inquiries elicited the fact that about a fortnight earlier he had been visiting a nephew who had at that time a severe attack of chicken-pox. I have not heard of any other cases of simultaneous appearance of herpes and varicella.

DR. C. H. SEDGWICK (Weedon) writes: A married woman, aged 30, consulted me on August 9th for a severe attack of herpes zoster affecting the inner side of the left arm and the left side of the chest. I warned her that possibly in two weeks' time her child, aged 7 years, might develop varicella, which would be an unfortunate sequel, as the family had arranged to go to the seaside on August 24th. On August 23rd this child was brought to me with varicella, the rash having appeared that afternoon.

DR. J. WALLACE (Weston-super-Mare) writes: At the request of Dr. Leonard Hill of this town I saw a case of concurrent varicella and herpes zoster, and he has given me permission to report it. The case presented two features of interest: (1) the simultaneous onset of the two eruptions, and (2) the rare simultaneous occurrence of the herpes on both sides of the body; for that reason it appears to be worth recording. A less remarkable point was the age of the patient, who was 42. Two of the man's children had chicken-pox, and at the end of a fortnight he came home from work feeling ill and suffering considerable pain, with a burning sensation over the back and side. When I saw him on the third day he had developed a chicken-pox rash of moderate severity and three patches of herpes—one under the angle of the left scapula (seventh spinal nerve), and two on the right side (tenth spinal nerve); each patch was rather larger than the face of an old-fashioned watch. These patches were still painful and burning, while the rest of the rash gave no special annoyance. The temperature the first day had been 103° F. In recent years much has been written for and against an etiological connexion between zoster and varicella. The weight of argument seems against it, and such a case as the above seems to add weight to the negative view, since it is comparable with cases of concurrent measles and chicken-pox, or measles and shingles, to which conditions, so far as I know, no one has attributed any etiological relationship.

CORRECTION.

OUR attention has been drawn to an error in the spelling of certain products which should have been attributed to the Energen Foods Co., Ltd.; not energin, as in the account of the Annual Exhibition in our issue of August 24th (p. 133).

VACANCIES.

NOTIFICATIONS of offices vacant in universities, medical colleges, and of vacant resident and other appointments at hospitals, will be found at pages 40, 41, 42, 43, 44, 45, 48, 49, and 50 of our advertisement columns, and advertisements as to partnerships, assistantships, and locumtenencies at pages 46 and 47.

A short summary of vacant posts notified in the advertisement columns appears in the *Supplement* at page 143.

EPITOME OF CURRENT MEDICAL LITERATURE.

Medicine.

203. Acute Febrile Coronary Angina.

IN a detailed study of acute febrile coronary angina, based on 34 personal cases, C. LIAN (*Paris Méd.*, July 27th, 1929, p. 86) describes the electrocardiographic signs in this disease. The characteristic departures from the normal may wholly or in great part disappear in the course of a few weeks or months; they are not of a morphological but solely of an evolutive order. Probably an absolutely normal electrocardiograph is not seen in acute febrile coronary angina, and, taken in conjunction with the clinical symptoms, these graphs are of great diagnostic importance. In three post-mortem examinations, lesions of obliterating coronary arteritis, due to a myocardial infarct, were found, and Lian's conception of this disease is that it is a syndrome comprising many forms of increasing gravity, corresponding to an attack of obliterating coronary arteritis with ischaemia or infarct of the myocardium, the infarct always being myocardio-pericardiac, cardiogastric, or infectious. The fever is due to autotoxic or infectious reactions which result from a cardiac inflammatory process. Acute coronary angina must be distinguished from that occurring in three other conditions: acute cardio-vascular states such as endocarditis and aortitis; sudden, acute cardiac dilatation; and vesicular crises, as, for example, hepatic colic. Cure is not rare in the myocardio-pericardial type, and is the rule in the myocardial and incomplete forms; only in cardio-gastric and infectious cases is the termination generally fatal. Grave prognostic factors are a stationary febrile curve, progressive diminution of arterial pressure, and persistence or accentuation of atypical ventricular electrocardiograms. Treatment should be directed to diminishing the myocardial ischaemia, to combating cardiac syncope, and to alleviating the pain. For the first of these, sodium citrate (by the mouth), benzyl benzoate, or papaverine is advised. Transthoracic precordial diathermy has been beneficial in some cases. As cardiac stimulants Lian uses digitalis by the mouth or by intramuscular injections, combined with subcutaneous injections of camphorated oil or coramine. In cases with intense dyspnoea and falling arterial pressure, intravenous injections of ouabain (1/8 mg. first, then 1/4 mg.) may be cautiously given. To alleviate the pains opiate injections are necessary. The patient should remain in bed, and later in his room for several weeks, and subsequently lead a life exempt from all effort. Lian advises that radiotherapy should only be given when the acute stage has passed, and only in cases in which an angina of effort remains as a sequel.

204. Streptococcal Carriers and Scarlet Fever.

E. A. LANE and EDITH A. BECKLER (*New England Journ. Med.*, June 20th, 1929, p. 1283), from comparative observations on children attending schools in districts where scarlet fever had been prevalent and children with no such history of exposure, came to the conclusion that there was no justification for regarding the presence of haemolytic streptococci in throat swabs as a reason for exclusion from school. Haemolytic streptococci were found to be fairly common among all groups of children, and of quite uniform prevalence in the months of February and March, when the experiments were made. According to the authors, until a sufficiently precise technique is available to identify the scarlet fever organism, and be sufficiently simple for general application, the control of scarlet fever must continue without the aid of throat cultures.

205. Intermittent Hydrarthrosis in Undulant Fever.

B. M. BAKER, jun. (*Arch. Int. Med.*, July, 1929, p. 128), records a case of undulant fever presenting the clinical syndrome of intermittent hydrarthrosis. A man, aged 47, complained of swelling of both knees which lasted about three days and then subsided, this sequence of events recurring in cycles of seven days with gradually increasing stiffness and difficulty in walking. Organisms of the *Brucella melitensis* group were repeatedly isolated from the blood and fluid in the knee-joints, and specific agglutinins appeared after the administration of an autogenous vaccine. Amelioration of the sub-[illegible] temporary alteration in the [illegible] appearance of the signs and [illegible] ease followed the administration of *Br. melitensis* vaccine and serum from a patient who had recovered from undulant fever. The author remarks that a differential diagnosis cannot be based solely on agglutination reactions in this case, since there were no agglutinins in the patient's serum during the period in which *Brucella melitensis* was being recovered from the blood and urine. The author concludes that the intermittent hydrarthrosis was part of a general infection by this organism, and suggests that infection by a member of this group may be the cause of the clinical syndrome—intermittent hydrarthrosis—in others, an association which has not before been recognized.

206. Chronic Meningitis.

W. R. GRAVES, ANNA D. DULANEY, and I. D. MICHELSON (*Journ. Amer. Med. Assoc.*, June 8th, 1929, p. 1923) report the thirteenth case of chronic meningococcaemia to be described in American literature. The remarkable features of this case, which occurred in a man aged 38, were the persistence of positive blood cultures for a period of five months, without any parallelism between the patient's general condition and recovery of the organism from the blood stream, and the absence of endocarditis or any other demonstrable focus of infection. The case belonged to the group of chronic meningococcaemias with late metastasis in meninges. The intermittent type of fever was present, but the periodicity was not regular, the rise occurring every day, or every second or third day. Serum treatment played only a minor part in the patient's recovery, as he received an unusually large amount of serum (380 c.cm. of polyvalent antimeningococcal serum intraspinally and 292 c.cm. intravenously), as well as 12 c.cm. of autogenous vaccine, without apparent benefit. The prognosis of chronic meningococcaemias is extremely favourable. Only three of the thirteen cases ended fatally, two patients dying from endocarditis and one from terminal meningitis.

Surgery.

207. Transplantation of the Ureter.

THOUGH the consensus of opinion among surgeons favours the non-operative treatment for bladder cancer, C. M. MCKENNA (*Surg., Gynecol. and Obstet.*, August, 1929, p. 174) is of the opinion that ureteral implantation is destined to become more popular in early cancer cases. He agrees with Coffey that this operation should not be used in the late cancer stage, because metastasis, hydro-ureter, and poor renal function are likely to follow. He also believes that the rectum is not so satisfactory a field for implantation as is the large bowel higher up. A study was made to determine the results as to kidney function, pathology, and bacteriology following ureteral implantation, and experiments were performed on fourteen dogs and one human subject, the Coffey technique being employed in each case. The results have led McKenna to the conclusion that this technique is the method of choice, and he urges a more extensive study of it with regard to kidney function, pathology, and bacteriology. In the treatment of bladder cancer, implantation of the ureter into the large bowel should be practised; this operation is the one of choice for exstrophy of the bladder. It is more important [illegible] velopment of a hydronephrosis than [illegible] nfection. The danger of hydronephros [illegible] by a change in the technique with reference to the muscularis and mucosa of the bowel. In the dog experiments the muscle at the site of the implantation was invaginated to permit healing to take place without impingement of the muscle of the bowel upon the ureter. Also a larger incision was made in the mucosa, and a suture inserted at the site of the introduction of the ureter into the bowel lumen to prevent pinching of the ureter by the mucosa.

208. Obliteration of the Hernial Sac.

J. S. K. HALL (*Med. Journ. and Record*, July 17, 1929, p. 61) records experimental and clinical investigations of the eradication of hernia by injections with the method originated in 1927 by Piña Mestre of Barcelona, who found in more than 8,000 cases that almost without exception the canal became closed and the hernia eradicated in from ten to fifteen days. The procedure is described as harmless and easy to carry out. The solution used was a combination of the alcoholic tinctures of catechu, monesia, krameria, dog-rose, and bilberry; all of [illegible] stimulating and astringe[illegible] [illegible]riments on animals it ap[illegible] dation and t[illegible] barrier effec[illegible] tion of the [illegible]

chosen as the site of injection, and around this, or into the inguinal canal, 5 c.cm. of the solution are injected daily for from six to fifteen days. After the second or third treatment the site of the injection becomes tender, and shows evidence of a reaction the severity of which varies in different cases. The formation of plastic tissue quickly suffices to prevent protrusion of the bowel, and within the next few days the orifice is obliterated. The treatment is said to be applicable to all types of hernia, and also in children and infants, its only contraindications being irreducibility of the hernia and haemophilia. Only 1 per cent. of recurrences has been reported, and Hall urges a thorough trial of the procedure in view of his own favourable experience.

209. Tumours of the Lung.

P. GELLEIN (*Norsk Mag. f. Laegevid.*, May, 1929, p. 473, and June, 1929, p. 569) records his observations on 39 tumours of the lung treated in two Norwegian hospitals during the period 1913-28. In only one instance was the tumour benign; in all the rest its malignancy was proved by necropsy (33 cases) or its clinical course (5 cases). Microscopical examination of 33 cases showed that 22 were carcinomata and 11 sarcomata. Of the carcinomata, 12 were primary, 8 secondary, and 2 uncertain; of the sarcomata, 3 were primary, 5 secondary, and 3 uncertain. The predominance of primary carcinoma is explained by the fact that only those tumours which gave rise to pronounced clinical symptoms were considered. The view that carcinomata had a predilection for the right lung was not confirmed by the present series, since among the 12 carcinomata 7 were in the left lung and only 2 in the right, while in 3 the localization was uncertain. The great majority (16) of the carcinomata occurred in women, partly owing to the presence of secondary tumours; apart from that 9 were in women and 3 in men. These figures are in opposition to almost all previous statistics, according to which primary carcinoma of the lung is much commoner in men than in women. The average age of the patients with pulmonary carcinoma was 60.9 years. The statistics of sarcoma were too small to justify any conclusion. The increase of carcinoma of the lung, to which almost all writers have drawn attention, is illustrated in the present series by the fact that during the period 1923–28 there were 9 cases among 19,672 patients, as compared with only 2 among 20,379 patients in the period 1916–22. No light was thrown on the etiology of the disease by the author's cases.

210. Carcinomatous Abscess of the Lung.

WHILE pulmonary excavations are most commonly due to tuberculosis or to abscess or gangrene of various etiology, neoplastic disease may be a cause, and M. FISHBERG and E. H. RUBIN (*Amer. Journ. Med. Sci.*, July, 1929, p. 20) report fifteen cases of primary cancer of the lung in which clinically and at necropsy cavities were found. About one-third of pulmonary neoplasms break down, leaving a cavity after the necrotic tissue is eliminated. The size of these cavities varies; some are quite small, others as large as a big orange, while in rare cases an entire lobe may be destroyed. The gross appearance of the necrotic tumour may resemble fibrocaseous phthisis, and the surrounding tissue usually presents an inflammatory area. Towards the periphery emphysematous lung tissue may be observed, but more frequently, owing to occlusion of the supplying bronchus, atelectasis of the alveoli is encountered. Concomitant active tuberculous lesions may be found, while fibrotic changes of the apical pleura due to old tuberculosis is very common. Metastasis to other organs is as frequent as in cancer without excavation. Cavity formation occurs mostly in primary tumours, and is uncommon in metastatic growths. Excavation of a pulmonary neoplasm may be the result of purely mechanical factors; the tumour, increasing rapidly, outgrows its blood supply, and anaemic necrosis of the central part ensues, the necrotic tissue being eliminated through the communicating bronchus. In such cases, however, this is usually the result [illegible] pyogenic organisms, spirochaetes, or [illegible] can be excluded by the absence of tubercle bacilli and the fetor of the sputum in cancer. Extensive tuberculosis of the lung is very rarely unilateral; in primary cancer this is the rule. Severe pain, and especially hyperaesthesia of the thorax, is not common in tuberculosis, while in malignancy it occurs in 90 per cent. of the cases. Dyspnoea, an early symptom of cancer, is not usual in tuberculosis. A flat note on percussion of the apex and down the side to the base is rare in tuberculosis, but the rule in cancer. The differential diagnosis of malignant abscess from those due to other causes is very difficult. The age of the patients, and the fact that in many cases of pulmonary abscess some cause, such as tonsillectomy or teeth extraction, is usually found, are diagnostic points. In all cases of apparently primary abscess of the lung of recent onset in elderly individuals the possibility of a broken-down neoplasm should be considered.

Therapeutics.

211. Localized Vaccine Therapy.

P. POINCLOUX (*Presse Méd.*, July 17th, 1929, p. 925) claims to have obtained striking results in vaccine treatment by a regional method of injecting the vaccine into the port of entry of the infecting organism—that is, the tissue by which it first entered the body. Thus, in gonorrhoeal arthritis, injections are not made into and around the joint, but into the walls of the urethral orifice, and, in otitis media, into the walls of the orifice of the Eustachian tube. Gonorrhoeal infections in the male are treated as just stated, and in the female by injections into Skene's glands. In *B. coli* infections injections are made into the mucosa of the colon with the aid of a proctoscope. Regional vaccine therapy is employed also in staphylococcal infections; thus in mammitis the vaccine is injected into the nipple. In cases of infection by multiple microbes, injections of one of these are first made, followed by injections of the other. In giving the injections a syringe graduated in tenths of a cubic centimetre, local anaesthesia with stovaine, and fine needles 5 to 6 mm. long are used, but these vary with the site treated. The initial dose of gonorrhoeal vaccine is 0.25 c.cm., which is increased by the same amount at each treatment. The initial dose of *B. coli* vaccine is 0.5 c.cm. A rise in temperature and malaise are noted after the first two injections. The reactions after injections of *B. coli* are less marked but more persistent than after gonococcal ones. Poincloux reports great success following this method in 185 cases of various infections, some of which are described in detail.

212. Sanocrysin in Tuberculosis.

K. SECHER (*Nordisk Medisinsk Tidsskrift*, June 1st, 1929, p. 342) gives a statistical analysis of his cases of tuberculosis treated with sanocrysin since November, 1923; with few exceptions, the seat of the tuberculosis was the lungs. Among the 191 patients who were cured, there were 53 in whom the disease was slight, and 41 in whom the disease was severe. There were also 70 cases of pleurisy, and 14 of glandular tuberculosis. Among the cured were also 13 children under the age of 15; the seat of the disease is not mentioned in these cases. In a second group, classified as improved, there were 68 patients; in 55 of these the disease was severe, and in 6 very severe. In the same group there were 3 cases of pleurisy, and 4 cases in children the seat of whose tuberculosis is not stated. In a third group, classed as unchanged or worse, there were 63 patients, in all of whom the disease was very severe; this class of case is said to be unsuited for sanocrysin treatment. The author criticizes the timid procedure of those whose maximum dosage is only 20 or 25 cg. He recommends a dosage carefully adapted to the needs of each patient, with due reference to the nature and extent of the disease, the weight of the patient, and his reaction to the previous injection; The interval between the injections must also depend on the behaviour of each case. With these reservations, the author recommends an initial dose of 50 cg., or about 1 cg. per kilo of body weight. The second dose is 75 cg. or 1 gram. The same dose is given at the third injection, and the intervals between these three first injections are two clear days. Later, each interval is five to six days. The injections are continued until no reaction is provoked, five or six injections being given as a rule. The average dose was 1.67 cg. per kilo of body weight. The author supports his advocacy of this treatment by references to the experimental work of Madsen and Mörch at the Serum Institute in Copenhagen.

213. Sulphur in Respiratory Affections.

DEALING principally with sulphur spring waters, LANGÉNIEUX (*Journ. de Méd. et de Chir.*, July 25th, 1929, p. 514) states that since olden times sulphur has been employed in respiratory affections as an antiseptic and especially as an expectorant. Sulphur has both a local and general action, and in affections of the upper respiratory tract produces markedly beneficial effects. Its antiseptic action rapidly dries up suppurations and converts a purulent into a mucous catarrh, which finally disappears. Its action on the pulmonary circulation increases leucocytosis, the respiratory exchanges, and the vitality of the mucosa. Sulphur furnishes to the mucus the requisite sulphur element and tones the mucosa, thus rendering it less liable to further attacks. It also exerts a beneficial general action on the system, which aids in the amelioration and cure of respiratory diseases. This medicament is indicated in all affections of the upper respiratory tract, such as rhinitis, pharyngitis, tonsillitis, and laryngitis. It is of marked benefit in chronic bronchitis, especially in the forms associated with cardiac and renal diseases, diabetes, gout, and syphilis. Asthma, however, does not respond to its administration, unless bronchitis is a predominant symptom.

Langénieux claims that the use of sulphur and sulphur water in respiratory disorders is particularly indicated in lethargic, lymphatic subjects; in neuro-arthritic, rheumatic, and gouty cases it should be combined with arsenical waters.

214. Serum Treatment of Malignant Pustule.

PARIS (*Presse Méd.*, July 24th, 1929, p. 959) believes that the dangers attending anthrax infection have been greatly lessened since the introduction of serum therapy, and reports a case of anthrax septicaemia in which striking results were obtained by the use of anti-anthrax serum. Large doses were employed, the initial one being 100 c.cm. This was increased to 230 c.cm.; the doses were then gradually decreased as improvement ensued. In all, the patient received 1,100 c.cm. of the serum, and, in order to prevent possible accidents, 3 grams of calcium chloride were administered daily. Anti-anthrax serum is said to be neither bactericidal nor antitoxic, and its mode of action is unknown. According to van Beneden it contains a sensitizing substance which, in the presence of a specific antigen, deviates the alexine: it activates phagocytosis, and, both *in vivo* and *in vitro*, is agglutinating and precipitating. In preventive doses it increases the resistance of guinea-pigs to anthrax; death is delayed, or is caused only by the injection of a dose larger than the minimum lethal one.

Laryngology and Otology.

215. Mastoid Syphilis.

Y. FRANCHINI (*Rev. oto-neuro-oftalmol. y de cir. neurol.*, April, 1929, p. 160), who records an illustrative case, states that syphilis may attack the mastoid process like any other organ or system in two ways—namely, either by creating a favourable soil for the pathogenic organisms by weakening systematic resistance, preventing the repair or cicatrization of other lesions, or by producing specific lesions locally. The former mode of attack is much the most frequent, as it is very common to meet with cases in which specific treatment by modifying the soil has a favourable action on the cicatrization of mastoid wounds and fistulae. Franchini's patient was a man, aged 32, the subject of inherited syphilis, who had had a mastoid operation three years previously and still had a mastoid fistula. Rapid recovery followed seven injections of mercury cyanide as the only treatment.

216. The Nose and Throat in Asthma.

F. M. RACKEMANN and H. G. TOBEY (*Arch. of Oto-Laryngol.*, June, 1929, p. 612) review the literature and discuss the present views of the significance of foci of infection in the nose, throat, and teeth in the causation of asthma. They divide asthma into the extrinsic form caused by some foreign substance, and the intrinsic, where no such factor is present. Of the asthma patients seeking relief at the authors' clinics 28 per cent. had had previous operations on the nose or throat irrespective of the intrinsic or extrinsic origin of the condition; 44 per cent. of asthma patients were found to have foci of infection in the nose, throat, or teeth. The authors recommend the radical treatment of all such foci, but have obtained permanent relief from asthma in only 5 per cent. of these cases. In spite of the poor prognosis they claim that proper treatment of the nose and throat is of real importance, and that there is no doubt that drainage of infected sinuses or removal of polypi has resulted in considerable general improvement of a large number of asthma patients. The authors explain the apparent absence of etiological significance of the infective foci in the nose in a large number of asthma patients by the suggestion that the sinus conditions and the polypi are part of the fundamental pathological changes that occur in asthma. They investigated fully two cases of sinus infection in asthma, and found that the sinus contents were bacteriologically sterile, but contained large numbers of broken-down eosinophil cells; these cells have also been found in nasal polypi of asthma patients.

217. Treatment of Oto-sclerosis.

ACCORDING to R. WOODS (*Journ. Laryngol. and Otol.*, June, 1929, p. 372) oto-sclerosis is the result of a chronic infection involving the joint surrounding the foot of the stapes. His method of treatment is based upon the principle underlying all cases of chronic inflammation—namely, the production of a suitable degree of acute local inflammation which can be strictly regulated, in order to avoid causing severe pain or any destructive effect on very delicate tissues. Intratympanic injections of liquor iodi (*B.P.*), diluted to one-tenth its strength, are recommended. These can be given almost painlessly behind the malleus with an instrument made by fitting a rubber teat, filled with the solution from a pipette, over a long needle, to the point of which a needle as fine as possible is soldered. Immediately after injection the vessels of the drum dilate; the pain develops to its maximum in about a minute and then slowly abates, disappearing altogether in a quarter of an hour. Injections are not made more often than once a fortnight, in order that the effects of the previous one may be allowed to pass off. From his experience with the above method, and also with radium emanations, the author's impression is that the former is most useful in early cases and the latter in old-standing ones. With the injections the improvement in hearing is often very great in the early cases, but in those of long standing but little good results. The difficulty of getting cases in their earliest stages arises because the onset is so insidious that patients are unaware of anything serious until tests show that deafness is well established.

Obstetrics and Gynaecology.

218. Obstetrical and Gynaecological Risks.

DISCUSSING obstetrical and gynaecological operative risks, R. PETERSON (*Journ. Amer. Med. Assoc.*, June 8th, 1929, p. 1907) states that an estimation of these is based on two factors: the nature of the operation, and the condition of the patient. Hence a most searching investigation must be made of the general condition of the patient. Two cases are instanced of simple operations in which the post-mortem examinations on patients of apparently normal physical condition revealed fatty degeneration of the heart. A good risk is defined as one in which the general condition of the patient is excellent and in which the local condition calls for an operative procedure which can be performed reasonably quickly without undue loss of blood. Such a patient will recover, and a fatality is attributable to operative inexperience or errors in technique. A poor risk is one in which an operation must be performed but the patient's chance of survival is not good or even fair. This class of risk includes patients with serious disease of the heart, lungs, or kidneys; those suffering from sudden or continued loss of blood; and those with long-continued suppuration, with absorption from cancerous disease, or septic absorption from any source whatever. Fair risks lie between these two classes, and any deviation may not necessarily change a good into a poor risk but only into a fair one. Organic disease of the heart or kidneys, while not precludir [illegible] nge the risk from good to fair, and [illegible] hether other than surgical treatment [illegible] as much and be far safer.

219. Local Anaesthesia in First and Second Stage Labour.

CITING Mackenzie's definition of referred pain, and Weiss and Davis's demonstration that this pain could be abolished by anaesthetizing the skin and so preventing any peripheral impulses from entering the hypersensitive centre in the cord, D. ROSE (*New England Journ. Med.*, July 18th, 1929, p. 117) states that, in labour, the contractions of the uterus set up repeated stimuli which cause the cord centres supplying this organ to become hyper-irritable. The normal or non-exaggerated skin impulses entering these irritable centres are recorded by the brain as pain arising in those skin areas. By accurately determining and infiltrating these areas with novocain, the perception of referred pain can be destroyed. Experimentally Rose has found that during the uterine contractions associated with labour pain is very definitely and clearly referred to three areas, and that this can be controlled by the intradermal injection of a sterile 2 per cent. solution of novocain. The important points are intradermal injection and the proper lines of infiltration; subcutaneous injection is of little or no value. Pain referred to the back is the least effectively relieved by novocain, due to reference from the dilating cervix and to pressure on the sacral plexus by the descending parts. Infiltration, therefore, gives only incomplete relief. The procedure is described, and tables are given of the results obtained in the first stage of 100 cases of labour and in the second stage of 80 cases. It is said to be applicable wherever inhalation narcosis is unsuitable; the contraindications are essentially only two: idiosyncrasy to the drug and a highly neurotic, intractable patient. Pantopon in combination with intradermal infiltration definitely prolongs the analgesia and has greater effect on the back pain. Rose asserts that this method, which is simple and safe, produces decided relief and absence of pain during first stage labour, and is decidedly valuable during the second stage. The analgesia has an average duration of three hours. Intradermal infiltration has no harmful effects on the foetus and mother as contrasted with other methods, and may be used in place of, or as an adjunct to, gas-oxygen inhalation during second stage labour. With proper asepsis and technique it is not harmful or dangerous [illegible]

220. Extra-peritoneal High Caesarean Section.

DESPITE the general agreement as to the advantages of cervical Caesarean section, B. J. KOUWER (*Gynécol. et Obstet.*, June, 1929, p. 418) favours the classical high method, and in the course of 216 operations has met with no case of actual or threatened rupture of the uterine cicatrix in subsequent pregnancies. The methods of several authorities are mentioned, and it is pointed out that by these sufficient protection is not given to the peritoneal cavity before opening the uterus. Kouwer advocates a modification of Lestocquoy's method. A large median incision is made in the abdominal wall, so that the umbilicus lies between its upper third and lower two-thirds. The peritoneum of the abdominal wall and the uterine serous membrane are then united by two rows of sutures, preferably of silk, the first being placed 2 or 2.5 cm. and the second 1 or 1.5 cm. from the free edges of the incision. The uterus then presents as an oval, 18 cm. long and 12 cm. wide. This method of suturing guarantees an absolute occlusion of the abdominal cavity, and takes only ten minutes to perform. The uterus is then incised in the long axis of the oval, the infant and placenta extracted, the cavity washed out with an antiseptic solution, and the uterine incision sutured. According to the conditions encountered, the abdominal incision is either partially closed or left entirely open. The method of further treatment varies with each case. Whatever the result of the operation may be, Kouwer always performs a subsequent laparotomy after complete involution of the genital organs has taken place in order to correct the artificial fixation of the uterus and, if necessary, of the uterine cicatrix. This operation, nine cases of which are reported, is said to be indicated in all cases in which the classical and cervical methods are considered too dangerous in view of infection, and, therefore, only embryotomy or Porro's operation remains.

Pathology.

221. Histology of Skin in Scarlet Fever.

N. KRITCH, A. PACHINE, and P. SIDOROW (*Arch. de méd. des enf.*, June, 1929, p. 313), record their observations on the skin of 109 cases of scarlet fever made during an epidemic at Moscow in the period 1924–27. During the eruptive period the epidermis shows certain changes as the result of the scarlatinal virus; the epithelial cells undergo a necrobiotic degeneration, causing an arrest of the physiological action of the skin, while the dermis presents an enormous vascular dilatation without any other sign of acute inflammation. After the eruption has faded there is a progressive development of the morbid process, and the degenerated cells of the epidermis become gradually transformed into a parakeratinized layer. In the dermis the accumulation of toxins gives rise to degeneration of the elastic fibres, and frequently to an infiltration of leucocytes round the vessels. Finally the parakeratinized epidermis becomes detached, and the skin presents a delicate pink colour. The epidermis now shows a few layers of young [illegible] while the degeneration of the elastic [illegible]tic infiltration in the dermis still per[illegible] the skin is very susceptible to extern[illegible]. These cutaneous lesions not only g[illegible] insufficiency of the skin, but also facilitate an accumulation of toxins, as the skin is deprived of its normal excretory power. In cases of severe scarlet fever, the lesions of the sweat glands may entail the arrest of their functions; the kidneys consequently become overtaxed, and in their turn undergo important changes.

222. Cancer and Magnesium Deficiency.

P. DELBET (*Bull. de l'Acad. de Med.*, July 2nd, 1929, p. 4) points out that, from its action on the nervous, digestive, and other systems, magnesium is evidently necessary for the human organism, and that this salt is deficient in certain of the present-day foods, such as bread. As it has been shown that magnesium possesses [illegible] advances the hypothesis th[illegible] may in part be due to a [illegible] Lamarre has proved that the coarser salt in common use twenty to thirty years ago contained 1.7 per cent. of magnesium, while the refined varieties now employed contain only 0.35 to 0.45 per cent.—an annual diminution for each person of 40 to 50 grams. Breteau has noted that coarse flour contains 62 mg. of magnesium per 100 grams, and the fine flour used in baking only 8 to 11 mg., while the discarded bran contains 70 to 116 mg. Perhaps a greater cause of magnesium [illegible]gress of agriculture. All plants contain [illegible] utilized for the synthesis of chlorophyll [illegible] So each harvest depletes the soil of this salt; a crop of sugar beet, for instance, removing about 90 lb. per acre. Moreover, this loss is not replenished by the use of magnesium fertilizers as other deficiencies are by the employment of nitrites and potassium. Delbet states that all cerebral work causes an elimination of magnesium by the kidneys; he considers that the stress of modern life causes a greater consumption of the salt by the nervous system than formerly, and, therefore, that an addition of magnesium to the food is advisable, especially for those of middle age. If these different causes of magnesium deficiency were eliminated, he maintains that the incidence of cancer would be notably diminished. A. KOTZAREFF, J. DE MORSIER, and A. MORIN (ibid., p. 11) confirm Delbet's deductions as to the effect of magnesium on cancer cells, and record the results of experiments on white mice engrafted with cancer. About half of these were given, every morning, a 4 per cent. solution of the salt with their food. It was found that this modified the evolution of the graft, but to a lesser degree than when injected subcutaneously. Intratumoral necrosis, with great liquid infiltration of the whole tumour and sometimes cystic formation, was very marked in the magnesium mice. Though not influencing the survival of the latter, it clearly prolonged life when given to mice that already had tumours.

223. The Hench-Aldrich Method of determining Blood Urea.

E. C. WHITE and H. C. RICKER (*Journ. Amer. Med. Assoc.*, April 20th, 1929, p. 1324) draw attention to the advantages of the Hench-Aldrich method for determining blood urea. The method, described two years ago (*Arch. Int. Med.*, October, 1926), is based on the mercury combining power of blood. The principle is the same as in the determination of salivary urea, and the method is said to be particularly useful in certain conditions, such as coma or dryness of the mouth, in which it is inconvenient or impossible to obtain the amount of saliva necessary to estimate the salivary index. The advantages of the Hench-Aldrich over the urease method are its rapidity and simplicity, and tests have proved that in no case was a clinical error made by its use. The original workers noted that their method gave high results in conditions of leukaemia and polycythaemia, and White and Ricker have found that in dogs fed on liver the results were much higher than those obtained by the urease method. Hench and Aldrich corrected this discrepancy in cases of leukaemia and polycythaemia by using plasma or serum and not whole blood, and by employing a different constant; this should probably be done also in cases of liver dieting. These clinical and experimental exceptions do not interfere with the general use of the method.

224. Experimental Herpes and Immunity.

S. NICOLAU and MME L. KOPCIOWSKA (*C. R. Soc. de Biologie*, June 7th, 1929, p. 334) immunized a number of rabbits against the herpes virus, and tested them by subdural inoculation of active virus. The immunized animals proved resistant, while control animals died in five or six days. Seven weeks after the last test the immune rabbits were again inoculated intracerebrally with herpes virus, there being eight control rabbits. One hour, 2, 6, 24, 48, 72, and 96 hours after inoculation an animal of each batch was killed; a suspension was made of its brain and inoculated subdurally into two normal rabbits. It was found that in the control rabbits the virus was uniformly demonstrable, whereas in the immunized rabbits it was impossible to demonstrate its presence more than two hours after inoculation. The authors consider that in the immune animals the virus is rapidly neutralized by the nervous tissues independently of the action of humoral antibodies. Histological examination showed that in immune animals the reaction reached its maximum within 24 hours, and that after this time degeneration of the polymorphonuclear cells was obvious.

225. The Widal and the Complement Fixation Tests in Typhoid Fever.

D. HERDERSCHÉE (*Nederl. Tijdschr. v. Geneesk.*, April 6th, 1929, p. 1708) has conducted comparative observations on the Widal and the complement fixation tests in a series of cases of typhoid and paratyphoid B fever with the following results. During the first fortnight the complement fixation reaction was positive in 11 and negative in 45 cases, while the Widal reaction was positive in 43 and negative in 20. In the later stages the fixation reaction was positive in 38 and negative in 31, and the Widal reaction was positive in 48 and negative in 25. The author's conclusions are as follows. The Widal test, especially when repeated, is of greater value than the complement fixation test in the diagnosis of typhoid fever. When a patient with a history suggestive of typhoid fever does not come under treatment until a later stage of the disease it is advisable to perform the complement fixation test at the same time as the Widal test.

FELAMINE

BRAND
SANDOZ

An association of the most powerful cholagogue—pure crystallised cholic acid—and the classical biliary disinfectant—hexamine, entirely free from accessory substances.

SANDOZ

THE SLEEPING PARTNER

There is one prescription which will send a patient to sleep naturally. There is one prescription which a patient will leave in the morning definitely better than when he took to it at night. It is the Staples Mattress. The Staples Mattress has been so designed that on it a patient may get the most rest and the most comfort. The springs support every part of the body *equally*. The spine is held straight. Distortion of the internal organs is impossible. Every muscle is fully relaxed, the nerves automatically follow suit. On a Staples Mattress sleep comes quickly and stays long.

FOR DEAFNESS
Doctors prefer "ARDENTE" because

1. It is individually fitted to suit the case for young, middle-aged, or old.
2. It is simple and true-to-tone, and leaves the hands free.
3. It removes strain, thus relieving head noises.
4. It conveys sounds from all ranges and angles.
5. It is entirely different, uncopyable, and carries a guarantee and service system.
6. It is suitable for "hard of hearing" or acutely deaf.
7. It is helpful for conversation, music, wireless, home, office, public work, and sports.

"ARDENTE" STETHOSCOPE.
Mr. R. H. Dent makes a Stethoscope specially for members of the medical profession suffering from deafness. Many are in use, and excellent results are reported on the latest, as evidenced by the interest shown at the last B.M.A. Meeting.

MEDICAL REPORTS.
Commended by all leading medical journals.—Mr. Dent will be happy to send full particulars and reprints on request.

ST. ANDREW'S HOSPITAL
FOR MENTAL DISORDERS,
NORTHAMPTON

FOR THE UPPER AND MIDDLE CLASSES ONLY.

President: THE MOST HON. THE MARQUESS OF EXETER, C.M.G., A.D.C.

Medical Superintendent: DANIEL F. RAMBAUT, M.A., M.D.

This registered Hospital is situated in 120 acres of park and pleasure grounds. Voluntary Boarders, persons suffering from incipient nervous and mental disorders, as well as certified patients of both sexes, are received for treatment. Careful clinical, biochemical, bacteriological, and pathological examinations. Private rooms with special nurses, male or female, in the Hospital or in one of the numerous villas in the grounds of the various branches can be provided.

WANTAGE HOUSE.

This is a Reception Hospital in detached grounds, with a separate entrance, to which patients and voluntary boarders can be admitted. It is equipped with all the apparatus for the most modern treatment of Mental and Nervous Disorders. It contains special departments for hydrotherapy by various methods, including Turkish and Russian baths, the prolonged immersion bath, Vichy Douche, Scotch Douche, Electrical baths, Plombières treatment, etc. There is an Operating Theatre, a Dental Surgery, an X-ray Room, an Ultra-violet Apparatus, and a Department for Diathermy and High Frequency treatment. It also contains Laboratories for biochemical, bacteriological, and pathological research.

MOULTON PARK.

Two miles from the Main Hospital there are several branch establishments and villas situated in a park and farm of 650 acres. Milk, meat, fruit, and vegetables are supplied to the Hospital from the farm, gardens, and orchards of Moulton Park. Occupation therapy is a feature of this branch, and patients are given every facility for occupying themselves in farming, gardening, and fruit-growing.

BRYN-Y-NEUADD HALL.

The Seaside house of St. Andrew's Hospital is beautifully situated in a Park of 330 acres, at *Llanfairfechan, amidst the finest scenery in North Wales. On the North-West side of the* Estate a mile of sea coast forms the boundary. Voluntary Boarders or Patients may visit this branch for a short seaside change or for longer periods. The Hospital has its own private bathing house on the seashore. There is trout-fishing in the park.

At all the branches of the Hospital there are cricket grounds, football and hockey grounds, lawn tennis courts (grass and hard courts), croquet grounds, golf courses, and bowling greens. Ladies and gentlemen have their own gardens, and facilities are provided for handicrafts, such as carpentry, etc.

For terms and further particulars apply to the Medical Superintendent (Telephone No. 56, Northampton), who can be seen in London by appointment.

THE COPPICE, NOTTINGHAM.
HOSPITAL FOR MENTAL DISEASES.

This Institution is exclusively for the reception of a limited number of **Private Patients** of both sexes of the **Upper and Middle Classes** at moderate rates of payment. It is beautifully situated in its own grounds on an eminence a short distance from Nottingham, and from its singularly healthy position and comfortable arrangements affords every facility for the relief and cure of those mentally afflicted. Voluntary Boarders received without Certificates.

For terms, etc., apply to the Medical Superintendent.

COURT HALL, KENTON, EXETER,
SOUTH DEVON.

For the care and treatment of Ladies suffering from Mental Diseases. Limited to eight patients. Telephone: Starcross 19.

CLIFFDEN, TEIGNMOUTH, in connection with Court Hall, for early and convalescent cases. Cliffden is a large well-appointed house, with lovely views of the South Devon Coast. It is beautifully situated in grounds of 19 acres. The gardens are very attractive, and there is a private road to the beach.

Resident Physicians: BERTHA M. MULES, M.D., B.S.; ANNIE S. MULES, M.R.C.S., L.R.C.P.

Telephone: *Teignmouth* 289.

HAYDOCK LODGE,
NEWTON-LE-WILLOWS, LANCASHIRE.

'Phone: 11 Ashton-in-Makerfield.
